Preface

To let our new employees and distribution partners have basic understanding about switching power supply, Mean Well published this “Switching Power Supply Technical Manual” based on our 22-year experiences in designing, manufacturing, and selling switching power supplies as well as the latest safety regulations and textbooks.

This manual includes basic information for switching power supply, general specifications, safety regulations, EMC standards, CE, reliability, operation notes, technical Q&A, and notes on failure correction. The contents emphasize on description of facts but not formulas or mathematical issues which is very suitable for people without S.P.S. technical background. Readers should get the big picture about switching power supply’s specification, application, and safety issues in the short time.

This manual was originated from “Switching Power Supply User Manual” published in February 1996 and was revised many times during these years. This edition strengthens the explanation portion by using photos, diagrams and tables which is more friendly to readers without technical background. Besides, the safety and EMC portion are also revised based on the latest standards that can help readers get more insight understanding about these regulations.

Finally, I would like to thank our editing committee that share their experiences in technical, research, engineering, quality assurance, repair, safety, and EMC fields to all of us. Since they are not professional writers, there might be some topics still unclear or hard to understand because of the “engineer-style writing ”. Please kindly give us your precious opinion so that we can improve the drawbacks in the next edition. Hope that we can provide more complete and valuable information in our future edition of technical manual.

Chapter 1
Introduction To Power Supply

1.1 Introduction To Linear Power Supply

The topology of a conventional linear power supply, as shown figure 1.1, uses a low-frequency transformer comprising a core made of silicon steel sheet to convert AC mains to a desired voltage, and rectifies and filters the voltage to a DC level. Since general equipments require stable DC voltage, the rectified and filtered DC level should be regulated through a power regulator. The power regulator clamps excessive voltage at the predetermined level and dissipates unwanted voltage in the form of heat. In order not to greatly reduce the efficiency, linear power supplies should put a limit to the variable range of the AC input voltage. The concept of linear power supplies is to clamp the unwanted voltage along with ripple voltage and dissipate them in the form of heat, which result in quite small ripple voltage. Due to linear topology, there will be no problems of ripple noise and EMI in linear power supplies.

Figure 1.1: The principle diagram of a typical linear (serial) power supply
Figure 1.2 shows a typical linear power supply with the main features indicated: (A) transformer comprising a core made of silicon steel sheet, (B) the big input capacitor, and (C) the big transistor with its heat sink.

![Figure 1.2: Picture of a linear (serial) power supply](image)

### 1.2 Introduction to Switching Power Supply (S.P.S.)

Switching power supplies mainly improve the weaknesses such as the huge volume, the heavy weight, and the low efficiency in linear power supplies. The topology of a switching power supply, as shown in figure 1.3, rectifies and filters the voltage directly from AC mains (off-line) without using a low-frequency transformer. The capacitance of the bulk capacitor can be quite small due to the high rectified voltage.

Switching power supply uses a high-frequency transistor to chop the high DC voltage (rectified from AC source) into high AC voltage and converts it into a desired voltage by a high-frequency transformer, and then rectifies and filters the voltage to a DC level. The high-frequency switching of the transistor and diodes results in generation of ripple noises at the transient of switching.
The efficiency is high, but will induce high frequency noise. Transistors operate in switching-mode, which is used for high frequency situations, small volume. Still has good efficiency at high voltage and low capacitance.

Figure 1.3: The principle diagram of a typical switching power supply

(2) The block diagrams along with their description in a switching power supply are as follows:

Figure 1.4 Block diagrams of a typical S.P.S.

(a) EMI Filter: The built-in filter reduces the EMI generated from the S.P.S.
(b) Inrush Current Suppressor: Inrush current occurs at the time of power-on of the S.P.S. If the inrush current is too large, the S.P.S. might be damaged, and the power distribution system could be adversely influenced. Thus, an inrush current suppressor is installed inside each S.P.S. to limit the high current.
(c) Input Rectifier: It rectifies the AC input voltage to a DC level.
(d) Power Factor Correction (PFC): The active/passive PFC circuit upgrades the power factor (PF) figure and approximates the waveform of input current to a sine wave, so as to be compliant to the harmonic current regulation and reduce reactive power.
(e) Converter: It converts the DC voltage to high-frequency signal, and the signal is increased or decreased by a high-frequency transformer.
(f) Output Rectifier: It rectifies the DC pulses to a steady DC level.
(g) Feedback Control: It regulates the output voltage to a steady level to respond to variation of loads and AC input voltage.

(h) Protection Circuit: When in abnormal situations, the S.P.S. will shut down or go into other protection modes by activating protection circuits. The protection circuits consist of over voltage, over temperature and over current (overload) protections, and etc.

For further explanation, refer to section 1.5

1.3 Comparison Between Switching Power Supply and Linear Power Supply

(1) Compared to linear power supplies, switching power supplies possess the advantages of high efficiency and light weight. The advantages correspond to the contemporary demands of being light and handy, and energy saving. Thus S.P.S. has gained much popularity in field applications.

(2) The following table is the comparison between S.P.S. and linear power supply:

<table>
<thead>
<tr>
<th>Items</th>
<th>Linear Power Supply</th>
<th>Switching Power Supply</th>
</tr>
</thead>
<tbody>
<tr>
<td>Efficiency</td>
<td>Low (25 ~ 50%)</td>
<td>High (65 ~ 90%)</td>
</tr>
<tr>

1.5 Circuit Principle of Switching Power Supply

(1) Introduction

Among all DC-to-DC converters, S.P.S. is to be divided into 3 basic circuit topologies based on input voltage, output voltage and polarity:

(a) Step-down or buck converter: Used for output voltage lower than input voltage.

(b) Step-up or boost converter: Used for output voltage higher than input voltage.

(c) Inverter or buck-boost converter: Used when the output polarity is reversed from the input one. It can also be used in either step-up or step-down application.
If the input side needs to be isolated from the output side, the above 3 basic converters would be inappropriate. Instead, the converter topologies, which are Forward, Flyback, Half-bridge, Push-pull, or Full-bridge, derived from the 3 basic ones would be the right ones to use. There are various methods of generating switching signal, one is to use self-oscillation whose oscillation frequency depends on input voltage and output loading, and the other is to use PWM IC whose oscillation frequency depends on the control IC.

(2) Circuit Principle

▲ Non-isolated Type

(a) Buck Regulator

When the switch (MOSFET) is ON, the energy is transferred to the load (RL) through L1 and stored in L1 at the same time; when the switch is OFF, the energy stored in L1 supplies the load through D1 and L1.

![Buck Regulator](image)

\[ V_o = \frac{V_{cc} \times t_{on}}{T} \]

- \( V_{cc} \): Input voltage
- \( V_o \): Output voltage
- \( t_{on} \): ON period of the MOSFET
- \( T \): Cycle
- \( t_{on}/T \): S.P.S. duty cycle

(b) Boost Regulator

When the switch (MOSFET) is ON, the energy is stored in L1; when the switch is OFF, the energy stored in L1 is transferred to the load (RL) through L1 and D1. Output voltage can be higher than the input due to the summation of the voltage pre-stored in L1 and Vcc. The topology is popular in PFC application.

![Boost Regulator](image)

\[ V_o = \frac{V_{cc}}{1 - \frac{t_{on}}{T}} \]
(c) Buck-Boost Regulator

When the switch (MOSFET) is ON, the energy is stored in L1. When the switch is OFF, the energy stored in L1 is transferred to the load (RL) through L1 and D1.

\[
V_o = \frac{V_c \times t_{on}}{T} \left(1 - \frac{t_{on}}{T}\right)
\]

\[
D > 0.5 \quad \text{ON} \quad | -V_o | > V_{cc} \quad \text{OFF} \quad | -V_o | < V_{cc}
\]

Figure 1.7: Buck-Boost Regulator

▲ Isolated Type
(a) Flyback Converter

When the switch (MOSFET) is ON, the energy is stored in the transformer; when the switch (MOSFET) is OFF, the energy in the transformer is transferred to the load (RL) through D1.

Figure 1.8: Flyback Converter
(b) Forward Converter

When the switch (MOSFET) is ON, the energy is transferred to the load (RL) and stored in L1 through D1 and transformer. When the switch is OFF, the energy stored in L1 is transferred to the load through D2. The topology of using two MOSFETs (Double-end) can reduce the voltage stress on the switches.

(c) Push-Pull Converter

When switch 1 (MOSFET 1) is ON and switch 2 (MOSFET 2) is OFF, the energy is transferred to the load (RL) through transformer and D2; when switch 2 is ON and switch 1 is OFF, the energy is transferred to the load through transformer and D1.
(d) Half-Bridge Converter

When switch 1 (MOSFET 1) is ON and switch 2 is OFF, the energy is transferred to the load (RL) through transformer, C2, and D1; when switch 2 is ON and switch 1 is OFF, the energy is transferred to the load through transformer, C1, and D2. The Asymmetric Half-Bridge Converter (commonly used in S.P.S. with PFC) derived from it can achieve higher efficiency.

(e) Full-Bridge Converter

When switch 1, 4 (MOSFET 1, 4) are ON and switch 2, 3 (MOSFET 2, 3) are OFF, the energy is transferred to the load (RL) through transformer and D2; when switch 2, 3 are ON and switch 1, 4 are OFF, the energy is transferred to the load through transformer and D1. The collocation of this topology and phase-shift control is commonly used to achieve high-efficiency Zero Voltage/Current Transition (ZVT/ZCT).
1.6 The Characteristics and Applications of Hard Switching Converters in S.P.S.

Existing varieties of topology in S.P.S. can be used to meet all types of demand. In theory, S.P.S. only has conduction loss and is without switching loss since it operates only at the ON/OFF period of the switch (MOSFET). However, in reality, the leakage inductance and the capacitance effect in components lead to the existence of switching loss, which is an obstacle to improving efficiency. The converters with switching loss are of the hard switching topology.

Chapter 1 Introduction To Power Supply

1.7 The Characteristics and Applications of Soft Switching Converters in S.P.S.

Soft switching technique is to reduce the switching loss coming from hard switching converters. By adding auxiliary and resonant circuits, switching transitions only take place either under zero-voltage or zero-current status. With significant decrease in switching loss, not only efficiency can be upgraded, but the temperature rise on switches can be reduced. Thus, plus the downsized heat sink, the power supply of new generation with minimized size and high power density is realized.

  - Magnetic Amplifier: QP-200/QP-150
1.10 Example of a Typical Switching Power Supply

Figure 1.13 shows a typical Forward circuit with PFC and PWM. The functionality of each block is as follows:

(1) Inrush Current Limiting - RTH1 (thermistor) suppresses the inrush current during cold start. Thermistor is a resistor whose resistance changes in indirect proportion to temperature, which is why it is called a NTC (Negative Temperature Coefficient) Thermistor. At cold start, the high resistance suppresses inrush current; after starting up for a while, the resistance decreases to reduce power consumption in normal operation. S.P.S. of middle/high power rating uses a circuit comprising TRIAC and relay to have lower conduction loss. Please refer to Section 2.3 for detailed information.

(2) Anti-Lightning Surge – ZNR1 (transient/surge absorber) is a resistive component. Part number 471, commonly used in our products, it possesses high resistance at normal condition. As the voltage across it increases, its conductivity also increases; the resistance decreases greatly when the voltage across it reaches 470VDC or 332VAC, and the conductive current is around 1mA. With that characteristic, the transient/surge absorber is able to bypass the abnormal surge voltage so as to effectively inhibit the surge voltage from entering the S.P.S.
(3) EMI filter – As shown in block (A) of figure 1.13 (excluding ZNR1, the surge absorber), this module of EMI filter is commonly used at the input side of our products to filter out noises interference. Basically, it consists of three types of components, which are X capacitor, Y capacitor, and common-mode choke. The functionality of each component in block (A) is as follows:
- C1 and C2 (X capacitor) suppress differential-mode noise.
- C3, C4, and C7 (Y capacitor) suppress common-mode noise.
- LF1 and LF2 (common-mode choke) suppress common-mode noise.

(4) Input Rectification – BD1 (bridge rectifier) rectifies AC input voltage to DC level with 120Hz ripple voltage.

(5) PFC (Boost) Circuit - Block (B) in figure 1.13 consists of Q1, D1, L1, and U1:1 (PFC controller) boosts the voltage to 380VDC. The main function of the block is for power factor correction, to approximate the waveform of input current to sine wave, and to reduce harmonic current to correspond to the demand of CE regulations. Either active or passive PFC circuits can be used. Passive PFC circuit uses a low-frequency transformer comprising a core made of silicon steel sheet to upgrade power factor figure from 0.5 to 0.7; active PFC circuit upgrades it to 0.95.

(6) PWM Control at Primary Circuit – Block (C) consists of U1:2 (PWM controller) and Q2 (main power transistor) converts DC voltage from PFC circuit to high-frequency pulse train signal, so as the high-frequency transformer can increase/decrease it to get lower conversion of output voltage.

(7) Isolation Transformer – Its (T1) main functions are isolation and decreasing voltage level. Temperature rise and the ability to meet withstand voltage rating of safety regulations are the main considerations when designing the transformer.

(8) Output Rectification – Block (D), consisting of D10, L2, and C12~C14, rectifies and filters the high-frequency DC pulses to a steady DC level.

(9) Feedback Control Loop – The loop, consisting of R74, PC1, etc., senses the divided output voltage to compare with the reference voltage of SHR1, and feedback the signal to PWM control IC (U1:2) through PC1 to regulate the duty cycle of PWM to achieve the purpose of output voltage control.

(10) Over Voltage Protection Circuit – It consists of ZD7, PC2, etc. When the output voltage exceeds the specified value (ZD7), PC2 conducts to activate SCR1 to pull the reference voltage of PWM IC (U1:2) to ground to cease operation of PWM IC, so as to protect the S.P.S or users’ system from damage.
(11) Snubber Circuit: RA and CA, located in primary side of T1 and secondary rectifiers (D10), are mainly to reduce the high-frequency spikes and oscillation coming from switching transitions of switches or rectifiers, such as Q2 and D10. It also improves EMI performance and decreases withstand voltage on components.
Chapter 2
Explanation of Switching Power Supply Specification

2.1 Input Voltage / Frequency

S.P.S. has been used in various field applications all over the world. Depending on type of product, input source of either alternating current (AC) or direct current (DC) is acceptable. Prior to operation of the power supply, users should confirm the following: the type of input voltage (AC or DC), the range of input voltage, and other conditions written on specification sheet. Input voltage exceeding the operating range would cause damage to the power supply. Also, input voltage with distorted waveform, even within the operating range, could also lead to malfunction of the power supply.

![Figure 2.1: Electricity around the world](image-url)
(1) If input voltage is of DC or square wave, its maximum value should be equal to 1.4 \(\sqrt{2}\) times of the peak value of sine wave. For example, input voltage of 85~264VAC can be replaced with DC voltage of 120~370V.

(2) Input source of DC or square wave is not acceptable for S.P.S. with function of input voltage auto-selection.

(3) Input Frequency:
The frequency of AC mains for S.P.S. is generally 50Hz or 60Hz. Taking into account deviation of \(\pm 3\)Hz from power plants, S.P.S. is designed to accept input frequency within the range of 47~63Hz. For special applications, such as for boats or ships, the frequency of 440Hz is acceptable, but users should be aware of the increased leakage current.

(4) The input range for products with safety approvals is available on model labels of the casings.

### 2.2 Input Current/Power Factor

It is common in S.P.S. designs to connect a bulk capacitor right after the bridge rectifier. This leads to charging of the filtering capacitor at the peaks of the input sine wave. Apparent power becomes high due to high RMS current and this leads to low PF.

Current meters with “True RMS” function are required for measurements of input current. PF for typical S.P.S. falls within the range of 0.4~0.6; for S.P.S. with PFC function, PF can be above 0.95. The relation among input current, output power, input voltage, power factor, and efficiency is as follows:

\[
\text{Input Current} = \frac{\text{Output Power}}{\text{Input Voltage} \times \text{Power Factor} \times \text{Efficiency}}
\]

### 2.3 Inrush Current

When AC is initially powered ON, a peak current is required to charge the empty bulk capacitor. This momentary peak is also called the inrush current.

The magnitude of the inrush current varies according to the type of current limiting circuit used. S.P.S. commonly uses a thermistor to limit inrush current. The high resistance of the thermistor limits inrush current at cold start of S.P.S.; the low resistance of the thermistor reduces power consumption after power-on. Thus, in order not to accumulate inrush current do not turn the power supply ON and OFF rapidly. Generally, after turning-off, a delay of few seconds before turning-on is suggested.
Compared to the input current in steady state, the inrush current could be several to
tens of times higher. Be aware that application with multiple S.P.S. leads to accumulate
inrush current. In this case, the ability of input wiring, external fuses, and switches to
withstand transient current should be taken into consideration.

![Inrush Current Limiting Circuit](image)

Figure 2.2: Circuit of input rectification and filtering

![Waveform of inrush current](image)

Figure 2.3: Waveform of inrush current

### 2.4 Line Regulation

The variation in output voltage, corresponding to change in input voltage, is called the
line regulation (measurement done with full load at output). Although the effect of line
change, within specified range, on output voltage would not be significant, minimizing
length of input wiring and limitation on the amounts of units connected to the same AC
source is recommended.

\[
\text{Line Regulation (\%)} = \left( \frac{V_{\text{max}} - V_{\text{min}}}{V_{\text{nor}}} \right) \times 100\%
\]

- \(V_{\text{max}}\): Maximum output voltage measured while input varies within the range
- \(V_{\text{nor}}\): Output voltage measured while input is at nominal level
- \(V_{\text{min}}\): Minimum output voltage measured while input varies within the range
2.5 Leakage Current
Leakage current is the current flowing from the protective earth (PE) conductor, such as metal enclosure, of equipments to frame ground (FG). Due to EMI requirements in S.P.S., there are Y capacitors (C2 and C3 in Figure 2.2) connected in between AC L/N and PE conductor. A low current will flow through the Y-caps to FG. In reality, leakage current should be regulated to comply with safety standards. In regulations of IEC60950-1 for IT products, leakage current should be less than 3.5mA for portable Class I equipment, 0.75mA for hand-held Class I equipment, and 0.25mA for Class II equipment.

2.6 Output Voltage/Tolerance/ Adjustment Range
The measurement of output voltage is defined to be at the output terminal of S.P.S. If voltage is measured at the load end, the measurement would deviate due to voltage drop on wiring. The voltage tolerance is the biggest voltage variation measured during simultaneous line and load change. In general, the tolerance accounts for line regulation, load regulation, cross regulation and setup tolerance. For compensating voltage drop, output voltage is factory set a little bit higher. Most products have a built-in variable resistor for output voltage adjustment. However, there are some important requirements to be followed:

(1) Rated power should not be exceeded. If output voltage is set higher, output current must be decreased accordingly.
(2) Rapidly decrease in output voltage with no load or light load would lead to momentary malfunctions of S.P.S.
(3) Output voltage would be unable to be set higher with low input voltage.
(4) Increasing the main output voltage of a multi-output model could have adverse effects on output voltage of auxiliary outputs such as extra power loss on auxiliary outputs (for auxiliary outputs adopting linear regulator or step down regulator).
(5) In addition to the built-in VR, high end models might also have the voltage trimming function using external resistors or voltage signal.

2.7 Maximum Output Current/Power
Maximum output power equals to Vout × Iout. Iout should be decreased to keep output power within rated value when Vout is increased. For instance, a model with rated voltage of 5V and maximum output current of 10A, the maximum allowed output current would be 9A while output voltage is set at 5.5V. Please note that the maximum allowed output current would remain at 10A even though output voltage is set at 4.5V.
Some channels of multi-output models would be allowed to deliver at the maximum value of output current range, but the total output power should not exceed rated value. For example, take D-60A with outputs of 5V@6A & 12V@4A, and maximum output power of 58W. If we use 5V output at 6A, and 12V output at 4A, the total output power would be 78W which exceeds the maximum value. Consequently, either output current of 5V or 12V should be decreased to keep output power equivalent to or less than 58W.

2.8 Ripple Noise

An AC waveform can be identified on the DC output of a S.P.S., which is shown in Figure 2.4.

![Diagram of Ripple and Noise](image)

Figure 2.4: Ripple and noise on the output voltage of a S.P.S.

There are two AC components, also known as Ripple and Noise (R&N), on the DC output. The first one, coming from sine wave rectification, is at a low frequency which is 2 times of the input frequency; the second one is at high frequency which is from the switching frequency. For measuring high frequency noise, configurations of an oscilloscope with a bandwidth of 20MHz, a scope probe with shortest ground wire possible, and adding 0.1uF and 47uF capacitors in parallel with test point for filtering out noise interference are required to be made.
2.9 Load Regulation

The variation in output voltage, corresponding to change in output load between minimum value and full value, is called load regulation. In general, high output current would lead to slight voltage drop at the output terminal.

\[
\text{Load Regulation (\%)} = \left| \frac{V_{\text{min}} - V_{\text{IL}}}{V_{\text{cent}}} \right| \times 100\%
\]

- \(V_{\text{min}}\): Output voltage at minimum load
- \(V_{\text{cent}}\): Output voltage at 50% load
- \(V_{\text{IL}}\): Output voltage at full load

2.10 Cross Regulation

For power supplies with two or more channels, cross regulation stands for the variation in output voltage of the channel under test which is loaded with 60% of its rated load, while the load of other channels varies between 20% and 100%.

2.11 Efficiency

The ratio of output power to real input power in terms of percentage.

\[
\text{Efficiency} = \frac{P_o}{P_{\text{in}}} \times 100\% = \frac{V_o \times I_o}{P_{\text{in}}} \times 100\%
\]

- \(P_{\text{in}}\): Real input power equivalent to \(V_{\text{in}} \times I_{\text{in}} \times PF\)
2.12 Set Up, Rise, Hold Up Time

Set up time (ton): The time from power on to 90% of rated output voltage, or from AC powered on to operation of S.P.S.

Rise time (tr): The time it takes for output voltage to rise from 10% to 90% of rated value. It is usually within 50ms. Longer period than that might lead to malfunction of system.

Hold up time (th): The time from power off to 90% of rated output voltage. The general requirement is at least 16ms to allow sufficient time for UPS to take over.

2.13 Overshoot, Undershoot

The deviation of output voltage to tolerance value prior to steady state after AC is powered on.
2.14 Transient Recovery Time
The time required for output voltage to settle within specified tolerance value while output load is in drastic change. The general requirement is 500us at most.

![Transient Recovery Time Diagram]

Figure 2.8: transient recovery time

2.15 Temperature Coefficient
It stands for the variation in output voltage due to change in ambient temperature. The unit is in terms of %/°C. Measurements are usually made after burn-in of half an hour.

\[
\frac{\Delta V}{V_0} / \Delta T \times 100\%
\]

\(\Delta V\): Variation in output voltage while temperature varies

\(V_0\): Output voltage measured prior to test conduction

\(\Delta T\): Variation in temperature

2.16 Over Current Protection (O.C.P)/ Overload Protection (O.L.P)
When the output power or current reaches the range of O.L.P./O.C.P. (typically 105%~150% of rated power/current), the S.P.S. would be protected by decreasing or cutoff of output power. The protection modes for over current/overload are categorized into the following types:

Protection Types:
(1) Foldback Current Limiting
   Output current is folded back to 20% or less of rated load current (curve (a) in figure 2.9).

(2) Constant Current Limiting
   Output current remains constant and within the specified range while the output voltage drops to a low level (curve (b) in figure 2.9).
(3) Over Power Limiting
Output power remains constant. As output load increases, output voltage decreases in proportion (curve (c) in figure 2.9).

(4) Hiccup Current Limiting
Output voltage and current keep pulsing ON and OFF repeatedly when protection is activated. The unit automatically recovers when fault condition is cleared.

(5) Shut Off
Output voltage and current are cut off when output load reaches protection range.

Figure 2.9: O.C.P./O.L.P.

Recovery Methods:
(1) Auto Recovery: S.P.S. recovers automatically when over current/overload condition is removed or over.
(2) Re-power on: S.P.S. restarts by manual AC re-power on after over current/overload condition is removed or over.

Cautions: Please prevent from long-term overload or short-circuit, or it could lead to decreased lifetime or damage of S.P.S. Some models are designed with two-stage protection for overload or short-circuit. When in the protection mode, S.P.S. is either foldback current limited or over power limited, and then goes into shutdown or hiccup current mode after a predetermined period of time.

2.17 Over Voltage Protection (O.V.P.)
When output voltage functions abnormality (e.g. lost of regulation), it could exceed the rated value. In consequence of that, O.V.P. is triggered to protect end equipments from damage. The protection modes for over voltage are categorized into the following types:
Protection Types:
(1) Shut Off
   S.P.S. restarts by manual AC re-power on of after fault condition is removed or over.
(2) Hiccup Voltage Limiting
   Output voltage keeps pulsing ON and OFF repeatedly when protection is activated.
   The unit automatically recovers when fault condition is cleared
   Basically, there are two kinds of O.V.P. detection:
   (1) Secondary detection circuit feeds back signal to disable PWM IC from operation.
   (2) Short circuiting output by using a Crowbar circuit. This would in turn trigger OLP.

2.18 Over Temperature Protection (O.T.P.)
   This protection is to prevent internal components of S.P.S. from overheating and damage, or to prevent decrease in lifetime due to high ambient temperature, overloading, or malfunction of S.P.S. (e.g. damaged cooling fan). The fault conditions needs to be cleared then S.P.S. would recover automatically or restarts by manual re-power on after internal temperature drops below activating temperature. In general, it would take a few to tens of minutes.

2.19 Vibration Test
   The test simulates the usage of S.P.S. in high vibration environment, and verifies the S.P.S.’s capability of operating under this situation. It is conducted with a single unit or an entire carton in the X, Y, and Z axes, and with sine wave acceleration of specified amplitude, frequency in each of the three axes at specified period of time.
   The relation between amplitude and frequency to constant G is as follows:
   \[ G = 0.002 \times d \times f^2 \]
   G: gravity, d: amplitude, f: frequency
   For example, if gravity is of 2G and d= 3mm, then f= 18 Hz
2.20 Hi-Pot Test

(1) Hi-pot testing is made on behalf of safety regulation, and is one way to verify the effectiveness of primary-to-secondary isolation of S.P.S., so as to confirm that the SPS can withstand high voltage without breakdown. The test voltage should be gradually increased from 0V to preset level and remains at preset level for 60 seconds. In mass production, the test period could be reduced to 1 second. If the leakage current flowing through the isolation material increases rapidly after applying test voltage, it indicates ineffectiveness of isolation (dielectric breakdown). Corona effect/discharge or transient electrical arc is not considered as a failure.

(2) When AC test voltage is applied, Y capacitors are the main cause of leakage current. A 4.7nF capacitor can cause leakage current of 5mA. According to regulations of UL-554, the Y capacitors should be removed for Hi-Pot test, which is not practical for mass production. The only solution is to increase the leakage current setting, typically 20mA, of test instrument. Presently, the criteria of leakage current are not defined in safety regulations.

(3) According to regulations of IEC60950-1, DC test voltage can be substituted when there are bridging capacitors coupled between primary and secondary circuits, so as to solve the problem of leakage current.
2.21 Isolation Resistance

It is to determine the dielectric strength of insulation materials by applying DC voltage. The unit is expressed in MΩ (mega-ohms). The tests are to verify the isolation resistance of transformers, PCB, and etc. The criteria of isolation resistance are not defined in IEC60950-1.

2.22 Power Good (P.G.)/ (Pok) and Power Fail (P.F.) Signal

When S.P.S. is powered on or off, PG/Pok, or PF signals are sent out for status monitoring.

P.G.: A TTL (+5V) signal will be sent out with a delay of 10~500ms after output voltage reaches 90% of rated value.

P.F.: The TTL signal will be turned off at least 1ms before the output voltage drops to 90% of rated value.

Pok: A TTL signal is sent out in synchronization with output voltage. It is without functionality in time sequence.

![Figure 2.11: P.G. and P.F. signals](image)

2.23 Alarm

The two contacts provided by S.P.S. are short-circuited when output voltage reaches specified voltage level. On the contrary, the contacts are open-circuited.

(1) The contacts of this alarm functions typically derives from solid-state semiconductor components. In addition to limitations on withstand voltage and current, polarity needs to be aware of.

(2) Some alarm functions use relays as the contacts. Since relays are just mechanically open/close contacts, it is free of polarity problem.
(3) Alarm functions could malfunction when the total output load is below 10% of rated current in parallel application of S.P.S.

2.24 Auxiliary Power

External power source may be required for S.P.S. with remote control or alarm function for status monitoring. For convenience of application, the power source is designed into the S.P.S.

(1) The auxiliary power source is designed based on isolation concept, and independent of other power sources in the unit.

(2) The auxiliary power source is only for applications of control functions in S.P.S. It should not be used as power source for other end equipments.
Chapter 3
Introduction To Safety

3.1 Introduction to Safety
To insure the safety of life and property, safety inspection of products becomes increasingly more important. UL/CSA/TUV safety standards are used to verify that the products meet safety requirements. Soundness of design, component selection, and overall quality are also checked at the same time. These safety standards mainly try to prevent the occurrence of the following six kinds of hazards: (1) Electric shock (2) Energy related hazards (3) Fire (4) Mechanical hazards (5) Radiation hazards (6) Chemical hazards.

3.2 Introduction to Regulations

3.3 Safety Marks found on MW products

(1) Considered as a component to be installed in a complete system. The File NO. E127738 is equivalent to compliance of UL1012.

(2) Considered as a component to be installed in a complete system. This mark represents universal certification. Both UL/CSA standards are met.

(3) Categorized as final product. This mark represents universal certification. Both UL/CSA standards are met.

(4) Based on the safety standard CSA C22.2 NO.60950, the file number issued to MEANWELL is LR109657. This mark represents universal certification, meaning UL/CSA/IEC/EN standards are met.

(5) Considered as a component to be installed on a complete system. Meets TUV requirements.

(6) Categorized as final product. Meets TUV requirements.

(7) Class II equipment.

3.4 Safety Related Terminology

(1) CB (Certification Body Scheme)
CB scheme is a global organization in which reports issued by any member nation is mutually recognized by all. Currently, there are 25 members from the European Union. CB reports and certificates can be issued by any one of the 51 national certification bodies (NCB). All certification bodies follow the same standards set by the IEC (International Electrotechnical Commission).

(2) LVD/ Low Voltage Directive (73/23/EEC) (93/68/EEC)
As early as 1973, the low voltage directive (73/23/EEC) was being followed by many countries in Europe. It regulates low voltage products between the range of AC 50V~1000V or DC 75V~1500V. Member countries individually authorized Safety lab to verify LVD on their behalf. On July 22, 1993, the EC organization announced that beginning in January 1, 1995 the CE mark (93/68/EEC) will be used to replace all safety marks previous certified by members of the EC.
(3) Safety-Extra-Low-Voltage (SELV)

This regulation applies to the secondary circuitry. The circuit should be designed to guarantee that under normal operating conditions, the voltage between any two touchable points should be less than 42.4Vpeak or 60Vdc. For class I equipment, it refers to “between any touchable point and the ground.” Under single fault conditions, the voltages between any two conductors of the SELV circuit and between any one such conductor and earth shall not exceed 42.4V peak or 60Vdc for a period longer than 0.2 seconds. Moreover, a limit of 71V peak or 120Vdc shall not be exceeded.

(4) Equipment Classification:

a. Class I Equipment:

   Equipment where protection against electric shock is achieved by using basic insulation and also providing a means of connecting to the protective earth conductor in the building where by routing those conductive parts that are otherwise capable of assuming hazardous voltages to earth ground if the basic insulation fails.

b. Class II Equipment:

   Equipment in which protection against electric shock does not rely on basic insulation only, but in which additional safety precautions, such as double insulation or reinforced insulation are provided, there being no reliance on either protective earth or installation conditions.

c. Class III Equipment:

   This type of equipment draws power from a SELV source which means hazardous voltages does not exist in its circuitry.

(5) Clearance Distance:

   The shortest distance between two conductive parts or between a conductive part and the bounding surface of the equipment as measured through air. Please refer to Figure 3.1.

(6) Creepage Distance:

   The shortest path between two conductive parts or between a conductive part and the bounding surface of the equipment as measured along the surface of the insulation. Please refer to Figure 3.1.
3.5 Category of Safety Tests (Refer to IEC-60950-1, including all S.P.S. related tests)

(1) Input Test
   The steady state input current of the equipment shall not exceed the rated current by more than 10% under normal load.

(2) Marking
   a. Rated voltage(s) or rated voltage range(s), in volts. (Should add on the "\(\pm\)" symbol for DC input).
   b. Rated current, in milli-amperes or amperes.
   c. Rated frequency or rated frequency range, in hertz.
   d. Manufacturer’s name, trademark or identification mark.
   e. Manufacturer’s model or type reference.
   f. Symbol \(\square\) for Class II equipment only.
   g. For equipment intended for connection to multiple rated voltages, the method of adjustment should be fully described beside the switch.
   h. Marking of fuse identification should be located adjacent to each fuse or fuse-holder and specify the fuse’s voltage rating, current rating and fusing characteristics.
   i. Symbol for grounding: \(\pm\) (IEC417 NO5017) or \(\square\) (IEC419 NO5019).
   j. Neutral conductor of the AC main supply shall be indicated by the capital letter N.

   Additional markings are permitted, provided that they do not give rise to misunderstanding.

(3) Capacitance Discharge Test
   Equipment shall be designed that at an external point of disconnection of the AC mains supply, the risk of electric shock from stored charge on capacitors connected in the primary circuit is reduced. Usually, there will be discharging resistors across the X-capacitors and decay their voltage to 37% of their original value within 1 second.
(4) **Humidity Test**

For insulating materials that their insulating characteristics may vary under different humidity, the humidity test should be made. Humidity test is carried out for 48 hours in a cabinet or room containing air with a relative humidity of 91%~95%. The temperature of the air, at all places where samples can be located, is maintained within 1°C between 20°C and 30°C such that condensation does not occur. And then the hi-pot test will be executed in this environment.

(5) **Working Voltage Measurement**

Parameters such as clearance distance, creepage distance, and value of hi-pot test derives from working voltage measurements.

(6) **Limited Current Circuit Measurement**

Limited current circuits shall be so designed that under normal operating conditions and in the event of a single failure within the equipment, the voltage should not exceed 42.4V peak or 60Vdc within the touchable region for repairing. So, as long as connecting to the limited current circuit, components with dangerous voltage will not harm human beings if the user accidentally touches it. For frequencies not exceeding 1 KHz, the steady-state current drawn through a non-inductive resistor of 2KΩ±10% connected between any two parts of a limited current circuit, or between any such part and earth, shall not exceed 0.7mA peak, or 0.2mA DC. For frequencies above 1 KHz, the limit of 0.7mA is multiplied by the value of the frequency in KHz but shall not exceed 70mA peak.

(7) **Grounding Test**

The purpose of grounding test is to make sure that the resistance between Protective Earth Conductors and grounded components does not exceed 0.1Ω. The test voltage should not exceed 12V. The requirement for TUV is 25A for 1min. As for UL, it is 40A for 2min.

(8) **Clearance Distance Measurement**

Minimum clearance distance is decided based on working voltage and insulation level. The test is conducted by applying a force of 10N to the internal components and a 30N force to the case to reduce the distances. We have to make sure that in the worst case scenario, the clearance distances are still within the regulated values.
Table 3.1 - Minimum clearances for insulation in primary circuits, and between primary and secondary circuits

</tbody>
</table>

1) The values in the table are applicable to FUNCTIONAL (F), BASIC (B), SUPPLEMENTARY (S) and REINFORCED (R) INSULATION.
2) The values in parentheses are applicable to BASIC, SUPPLEMENTARY or REINFORCED INSULATION only if manufacturing is subjected to a quality control programme that provides at least the same level of assurance as the example given in annex R.2. In particular, DOUBLE and REINFORCED INSULATION shall be subjected to ROUTINE TESTS for electric strength.
3) For WORKING VOLTAGES between 2 800 V peak or d.c. and 42 000 V peak or d.c., linear interpolation is permitted between the nearest two points, the calculated spacing being rounded up to the next higher 0.1 mm increment.
(9) Creepage Distance Measurement

Working voltage measurement in conjunction with insulation level can be used to find out what is the minimum creepage distance based on Table 3.3.
Example: If the input voltage is 240VAC and the voltage between the primary circuit and secondary circuit is 275Vrms, 600Vpeak, what are the minimum creepage and clearance distances under the situation of Pollution Degree 2 and Insulation Material Group III by using Linear Interpolation Method? (Please refer to Tables 3.1, 3.2, & 3.3).

Ans: Creepage : \( 2.5 + \frac{(275 - 250)}{(300 - 250)} \times 0.7 \)

\[ = 2.5 + 0.35 \]
\[ = 2.85 \]
So, it is 2.9 mm for Basic Insulation and 2.9 mm \( \times 2 = 5.8 \) mm for Double Insulation

Clearance : \( 4.0 + 0.6 = 4.6 \) mm

(10) Limit Power Source Test

When an electronic circuit is powered by a limit power source its output current and power are under the limitation shown in Table 3.4, the risk of fire can be reduced significantly. So, the safety distances and flammability rating of components can be much lower. For LPS products, we can use plastic of the HB level as the material for its enclosure to reduce costs.

Table 3.4 – Limits for inherently limited power sources

</tbody>
</table>

1) \( U_{DC} \): Output voltage measured in accordance with 1.4.5 with all load circuits disconnected. Voltages are for substantially sinusoidal a.c. and ripple-free d.c. For non-sinusoidal a.c. and d.c. with ripple greater than 10% of the peak, the peak voltage shall not exceed 42.4 V.

2) \( I_{SC} \): Maximum output current with any non-capacitive load, including a short circuit, measured 60 s after application of the load.

3) \( S \) (VA): Maximum output VA after 60 s of operation with any non-capacitive load including short circuit.
(11) Stability Test
The test unit shall remain balanced when tilted to an angle of 10° from its upright position. This is to make sure that this condition will pose no danger to the user or repair personnel.

(12) Impact Test
A product consisting of complete enclosure should pass the impact test. A solid smooth steel ball, approximately 50mm in diameter and with a mass of 500g±25g, is permitted to fall freely from rest through a vertical distance of 1.3 meter. After test completion, the product must not be capable of inducing danger or show insufficient insulation.
(13) **Drop Test**

For hand-held and direct plug-in equipments, a sample of the complete equipment is subjected to three impacts resulting from being dropped onto a horizontal hardwood surface. The drop height should be 1 meter and the sample can’t induce any danger or show insufficient insulation after testing. However, it is not required that the sample can still function properly.

(14) **Mold Stress Relief Test**

Enclosures of molded or formed thermoplastic materials shall be so constructed that any shrinkage or distortion of the material due to release of internal stresses caused by the molding or forming operation does not result in the exposure of hazardous parts or in the reduction of creepage distances or clearance distances below the minimum requirement. The test temperature is 70°C or 10°C higher than the surface temperature measured during the Heating Test. The test duration is 7 hours.

(15) **Heating Test**

- The first step is attaching thermocouplers to test components.
- Apply 90% and 110% of rated input voltage.
- Full Load connected at output terminal.
- The test should stop only after the temperature is stable.

The maximum allowable temperature for each component is as follow:

- **(A)** General electronic components: the rated operating temperature for that component.
- **(B)** Transformer: Class A → 90°C  
  Class E → 105°C  
  Class B → 110°C
- **(C)** Case: Metal 70°C; plastic 95°C.

(16) **Ball Pressure Test**

This test is mainly for plastic material. Using a solid smooth steel ball, approximately 5mm in diameter and applying a 20N force on the test surface. Both items are placed in a heating cabinet at 125°C for 1 hour. It is then taken out of the cabinet and allowed to cool down to room temperature. The diameter of the indentation can’t exceed 2mm. If the material is Phenolic, the Ball Pressure Test can be omitted.

(17) **Leakage / Touch Current Test**

Test voltage is 1.06 times of the rated voltage and the leakage current can’t exceed the limits of the following table:
Table 3.5 - Maximum current

<table>
<thead>
<tr>
<th>Type of Equipment</th>
<th>Maximum Touch Current</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class I Hand-held</td>
<td>0.75mA</td>
</tr>
<tr>
<td>Class I Others</td>
<td>3.5mA</td>
</tr>
<tr>
<td>Class II All</td>
<td>0.25mA</td>
</tr>
</tbody>
</table>

(18) Electric Strength Test

The purpose is to make sure that the insulation materials in the equipment have enough electric strength. Two portions of the sample will be tested: isolating transformer and switching power supply. The voltage applied is gradually raised from zero to the prescribed voltage and held at that value for 60 seconds. Insulation breakdown is not allowed during the test. The general standard is 3 KV for primary to secondary.

(19) Abnormal Test

Equipment shall be designed so that the risk of fire or electric shock due to mechanical or electrical overload or failure, or due to abnormal operation or careless use (fan lock, open or short of MOS, diode, or capacitor), is limited to a minimum. After abnormal operation, the equipment shall remain safe for an operator, but it is not required that the equipment should still be in full working order. There’s no specific time duration for this test, however, we can stop the test only after one of the following situations occur:

1. The fuse is open.
2. The outcome is clear.
3. The test has been made for 7 hours.
4. The input current or temperature has reached equilibrium situation.
5. Flame or the melting metal has been spreading outside the case.

(20) Output Power Overload Test

While testing, input voltage is at the maximum rated input voltage and the output load for each channel is increased gradually until over load protection occurs. Following conditions are not allowed during the test:

1. Flame has spread outside the equipment.
2. The case changes its shape and influences safety.
3. Temperature of the transformer exceeds the limitation: Class A - 150 ℃; Class B - 175 ℃.

Chapter 4
Introduction To EMC

4.1 Introduction of EMC

EMC (Electromagnetic Compatibility) is divided into two sections, which are EMI (Electromagnetic Interference) and EMS (Electromagnetic Susceptibility).

By definition, EMI refers to emissions of electromagnetic energy from a device or system that interferes with the normal operation of another device or system. On the other hand, EMS refers to the ability of a device or system to function without error in its intended electromagnetic environment.

4.2 Regulations and Explanations of EMI

(1) If the functionality of an electrical device is interrupted by external voltage/current sources, and the device cannot function as intended. Then, we can conclude this device is being interfered by electromagnetic wave. For example, the picture on TV may distort when a nearby PC is starting up; a radio may send out noises if a motorcycle is starting while the radio is operating. These phenomenons are considered as electromagnetic interference. There are two ways that un-intentional external voltage/current sources causes interference: The first one is Conducted Emission – this source of noise interferes with other systems through power cord, plug, and dispatching system; the second one is Radiated Emission - this source of noise interferes with other systems through the radiation of its electromagnetic field. That is, radiates unwanted electromagnetic wave through free space.
(2) The most popular EMI regulations are CISPR22/EN55022, and the limits are listed on the Table 4.1.

**Table 4.1: Limit for Conducted Emission of class B equipments**

<table>
<thead>
<tr>
<th>Range of frequency (MHz)</th>
<th>Limit in dB (uV)</th>

</tbody>
</table>
4.3 Definition of Harmonic Current and Related Regulations

(1) For a traditional AC/DC converter, there is a bridge rectifier and bulk capacitors which charges/discharges in a very short period of time. Hence, a high current pulse is introduced at AC input line and generates harmonic current noises through the power line. The un-intentional harmonic current noise could interfere with other electrical devices and also reduce the Power Factor (See Figure 4.3). In order to prevent interference with other equipments, PFC (Power Factor Correction) circuit should be used on the switching power supply that makes the current waveform more sinusoidal (Figure 4.4), and improves the quality and efficiency of the AC power source.

![Figure 4.3](image1.png)
Non-PFC: Typical Pf<0.6

![Figure 4.4](image2.png)
PFC: Typical Pf>0.9
(2) Since, harmonic current pollution on power distribution network is becoming more and more serious. CENELEC announced the latest standard EN61000-3-2:2000 to regulate harmonic current. All members of the European Union began to execute the regulation on July 1st, 2001, and official enforcement of this regulation commences after Jan 1st, 2004. This regulation divides all applicable products into four categories:

Class A: 
- Balanced three-phase equipment
  - Household appliances excluding equipment identified as class D
  - Audio equipment
  - Equipment not specified in one of the three other classes

Class B: 
- Portable tools
  - Non-professional Arc welding equipment

Class C: Lighting equipment

Class D: PCs, monitors, and TV receivers with a specified power less than or equal to 600W
(3) If MW power supply is not used in Class D equipments, than any products with input power <150W are able to meet Class A Limit (Table 4.3) without the PFC circuit. For input power >150W, power supply will need PFC circuit in order meet Class A and Class D limits.

**Table 4.3 : Limits for Class A equipment**

<td>Voltage Dips, short Intermittence</td>
<td>Simulating how voltage dips, interruptions or variation of the AC source affect the electronic products</td>
</tr>
</tbody>
</table>

4.5 Introduction to EMC Regulation:

(1) Currently, most countries implement their own EMC regulations. In general, all the regulations are based on the standards issued by international committees, such as IEC (International Electrotechnical Commission), and CISPR(Committee International Special des Perturbations Radioelectraque). Individual countries adapt these international standards, and modify it to include the actual need for that particular environment.

(2) Following are the EMC standards issued by European Union for each product category:
<table>
<thead>
<tr>
<th>Product Category</th>

*Remark:
Criterion A: The function of equipment under test is not influenced or only deviates within a certain range during or after the test.
Criterion B: The function of equipment under test is influenced or even loses its function during test conduction. However, it will recover automatically after the test is over.
Criterion C: The equipment loses its function during test conduction or after testing. It can’t recover automatically and need to be manually re-powered ON.
Criterion D: The equipment loses its function during or after the test and it can’t recover even by manual re-power ON.
4.7 EMC Tests: Procedure And System Allocation

Refer to CISPR22, IEC61000-4 regulation, and Meanwell EMC reports for detailed information.

(1) Conduction Emission

1. If the power cord can not be shrunk to a suitable length, so that it is 40cm above the metal plane. The excess wires should be bundled to a length of 30~40cm.
2. Simulated resistive network should be attached to the ground plane before connection to the EUT.
3. Simulate connection to external environment through I/O cables.
4. Auxiliary devices should be placed 10cm apart.
5. Auxiliary and control equipment should be placed 10cm apart. The power cord should be 1m long with no shielding.
(2) Radiation Emission

1. If the power cord can not be shrunk to a suitable length, so that it is 40cm above the metal plane. The excess wires should be bundled to a length of 30~40cm.
2. The power box should be installed on a metal plane and parallel to ground. The simulated resistive network should be placed under the horizontal metal plane.
3. The power cord should be laid flatly on the ground before connecting to the power outlet. Extension cord should not be used.

Test procedure
1. According to CE directive, EUT should be placed on a rotating table 10m from the antenna (power cord shall hang loosely from the longer side of the table). It will be rotated in 360 degrees to pick out angles with the strongest radiation. The antenna will also be raised between 1~4m to pick out the highest radiation.
2. Antenna must be adjusted for horizontal and vertical testing.
3. The test frequency is between 30~1000 MHz.
(3) Voltage Fluctuations and Flicker

1. Set the output of Power Analyzer to 230V/50Hz
2. Testing periods are 1) Short time $T_p=10$min and 2) Long time $T_p=2$hrs
3. Power Analyzer will collect all the measured data and reports the result.
(4) ESD (Electrostatic Discharge)

Test Procedure
Apply ESD to EUT’s conduction and coupling surface.
1. The EUT shall be subject to 200 contact discharge. 100 times each for negative and positive discharge.
2. Pick four test points.
3. Center of EUT and side of HCP should be subjected to contact discharge of 50 times.
4. Other 3 points should be tested 50 times each.
5. If there are no conductive surface to make contact discharge, test can be done on the coupling plane (HCP, VCP). 200 discharges also need to be done.
6. Air discharge will be performed at slots, apertures, and insulation surface.
   1) Points selected should be based on actual operating conditions.
   2) A minimum of 10 air discharges per test point.
Setup
1. Test shall be conducted in a special chamber lined with radiation absorbing plates.
2. Antenna is set at 1m above ground.
3. Antenna is placed at 3m from EUT.
4. EUT placed at 80cm above ground on a non-conducting surface.

Test procedure
1. A signal from the signal generator is sent through an amplifier to magnify it to the required level and then projected from the antenna. The EUT is subject to this radiated interference.
2. EUT is rotated either left or right to be tested on four faces.
3. The Antenna will be adjusted between horizontal and vertical directions.
4. The test frequency is between 80~1000MHz.
(6) EFT (Electrical Fast Transient)

Setup
This test also needs to be executed on the reference ground plane and we only have to connect our sample to the equipment and select the test program.

Test procedure
The testing equipment will send out a 5 KHz continuous waveform for 15ms and we have to check whether it could cause a fault during power supply operation.
(7) Surge

Setup
1. This test should be executed on the reference ground plane.
2. EUT should be place 80cm above ground on a non-conducting table.

Test procedure
1. The purpose of this test is to make sure that the power supply will not fail when a simulated surge is inserted through the AC source.
2. Connect AC source to the test sample and select the test program.
(8) CS (Conducted Susceptibility)

Test signal send through AM modulator (1 kHz, 80%)

Setup
1. This test also should be executed on the reference ground plane and the power supply will be put on a non-conductive object which is 10cm away from the ground.
2. The power cord should be made a short as possible.

Test procedure
Signal generator will send out a signal to the power supply through CDN (Coupling Decoupling Network) and we have to check whether a fault condition occurs to the power supply.

<table>

<td>Special</td>
</tr>
</tbody>
</table>

× is an open level.
(9) **MF (Power-Frequency Magnetic Field)**

**Setup**
This test is executed on a reference ground plane and the power supply should be located 10cm above this plane.

**Test procedure**
1. Test equipment will send out a certain current flowing through the antenna surrounding the power supply. We have to check whether a fault condition occurs to the power supply due to the magnetic field induced by the current.
2. Place sample within the antenna and proceed with the test.
3. The antenna will be adjusted to the X, Y, and Z axis.
(10) DIP (Voltage Dip / Interruption)

Setup
This test should be executed on a reference ground plane. We only have to connect the power supply to the test system and the pre-set program will automatically execute the test.

Test procedure
The purpose of this test is to change the power quality supplied to the sample unit and check whether it would fail under this interference.
1. Check influence of voltage dip/interruption on test sample.
2. Dip > 95% → 0.5 cycle (10ms)
   Dip 30% → 25 cycles (500ms)
   Interruption > 95% → 250 cycle (5000ms)
Chapter 5
Introduction To CE

5.1 Introduction to CE Marking
The European Union introduced the “CE mark” in an effort bring awareness to the need for health, safety, and environmental protection. Through CE marking, consumers will know which products are designed with their best interest in mind. Generally speaking, all products with safety concerns must have the CE mark in order to be exported to countries in the EU. Products bearing the CE mark can be traded freely in European member countries without being subjected to duplicate inspection process.

5.2 Related Directives of CE Marking
Presently, the European Union had put in effect around 20 directives in several different fields, such as low voltage, toy, industrial machinery, medical equipment, EMC, and etc. Among these, low voltage and EMC directive are related to the S.P.S.
(1)Low Voltage Directive (LVD): L.V.D. was strictly enforced starting in 1997. It regulates electrical products within the voltage range of 50~1000 VAC / 75~1500 VDC. In terms of S.P.S., L.V.D. shares the same standards as other safety regulations. For instance, by meeting the ITE requirements of EN60950-1, you will also automatically fulfill LVD.
(2)Electro-Magnetic Compatibility (EMC): EMC consists of EMI (Electro-Magnetic Interference) and EMS (Electro-Magnetic Susceptibility), it was strictly enforced starting in 1996. Products with transformers and electronic control circuits are all regulated by this directive.
5.3 CE Compliance

The “CE Mark” is not issued by any particular regulatory agency. Manufacturers can declare conformity by fulfilling directives related to their field. For instance, the self declaration certificate of an electronics manufacturer will be composed of a list of directives that were satisfied. This is the only prerequisite for showing the CE mark. However, if a product was found non-confirming from random market inspection, the manufacturer may be asked to stop sales and recall previously sold units.

5.4 How Mean Well Test CE Related Regulations

For L.V.D., Mean Well products are certified by authorized third party/organization (such as UL, CSA, and TUV). As for the EMC portion, an authorized laboratory will certify the product based on setup and test procedure specified by Mean Well. An EMC report will be provided by the lab showing which directives were met. Mean Well is ultimately responsible for issuing its own CE declaration of conformity.

SPS are components meant for powering complete systems. EMC performance is dependent on how the SPS is assembled in the system. It is recommended that the end user recheck EMC after installation. Majority of our customers use metal enclosures for their system. We try to simulate that type of setup by mounting both the power supply and load to a metal plate. If the enclosure of the system happens to be made out of plastic or the setup is significantly different from ours. There is a good chance that the EMC results will be completely different from what is found on our test report.

Please refer to Figure 5.1 for EMC setup:

A conductive metal plate (galvanized steel) is used to simulated end user’s enclosure. The standard dimension is 36 x 36 cm. A 23 x 23 cm plate may be used for low wattage units. As for high wattage units, a 72 x 32 cm plate may be used. The test setup will be mentioned clearly in the EMC Report.
EMC test method and setup:

Figure 5.1: Standard setup for EMC test

The “CE marking” is a permit for products to enter the European market. Once our company signs the CE Declaration for a certain product, this means that the product meets the requirements of LVD and EMC directives.
Chapter 6
Reliability

6.1 Curve of Lifetime and Failure Rate
High reliability of switching power supply has been proved from its extensive use in household appliance and industrial equipment. The industrial sector holds SPS in high regards. Figure 6.1 is a typical curve of product lifetime and failure rate (Bath-Tub Curve).

![Bath-Tub Curve](image)

Figure 6.1: Bath-Tub Curve

(1) Initial Failure Period
To prevent “initial failure”, all manufacturers have sifted the defective components out by making burn-in tests. Normally when customers receive the S.P.S., it has already entered the “random failure period”.

(2) **Random Failure Period**

The stability of the S.P.S is related to its reliability (MTBF: Mean Time between Failure) and generally speaking, the failure rate is very low. But, the random failure rate has a lot to do with user’s installation and operating conditions (ambient temperature, derating, ventilation, and vibration).

(3) **Fatigue Failure Period**

After the “random failure period”, S.P.S is going to have higher failure rate and enters the “fatigue failure period’. At this time most of the components have aged (such as fans, aluminum electrolytic capacitors) and hence induce failure.

### 6.2 Ambient Temperature and Components’ Lifetime

(1) High frequency and high efficiency switching technology, improvement of components, and integration with up to date technology can reduce the size of the S.P.S. But, components must also populate the PCB at higher density. The lifetime of components on a S.P.S. will vary significantly due to differences in ambient temperature. When an electrolytic capacitor is used for filtering, its internal chemical reaction will raise the surface temperature. Lifetime of the electrolytic capacitors is sensitive to ambient temperature.

(2) In general, the lifetime of the electrolytic capacitors will be reduced by half for every 10°C increase in the ambient temperature. On the contrary, when temperature goes down 10°C, its life time will be doubled. Figure 6.2 describes the relationship between lifetime of the power supply and ambient temperature. If the S.P.S. is continuously operated in high temperature environment, the electrolytic capacitors will enter the “fatigue failure period” earlier while in the mean time the other components are still at the “random failure period”. To extend the lifetime of this S.P.S., we need to replace all the electrolytic capacitors.
Chapter 6 Reliability

Figure 6.2: Lifetime of the power supply versus ambient temperature

(3) Estimation of Electrolytic Capacitor’s Lifetime (Based on output capacitors).

\[ \text{Ln: } Lo \cdot 2(Tm - Tn)/10 \cdot 2^{\left(1-(ln-Im)^2\right)} \]

Ln: expected lifetime of the electrolytic capacitor.
Lo: lifetime of the electrolytic capacitor working at maximum temperature and maximum ripple current.
Tm: accepted maximum ambient temperature of the electrolytic capacitor.
Tn: surface temperature of the electrolytic capacitor (through measurement)
Im: accepted maximum ripple current of the electrolytic capacitor at Tm.
In: working current of the electrolytic capacitor.
r: experimental constant (for CE04 type, r = 0.3)

(4) In models with built-in fan, the lifetime of the fan is also related to operating temperature. Higher the ambient temperature leads to shorter lifetime. After a certain period of time, the fan should be cleaned or replaced because its bearing may wear out or dust may stick to the blades.

6.3 Ambient Temperature and Frequency of Return for Repair

Electronic technology has been developing at an astounding rate leading to more S.P.S. being used in all types of system. Although the lifetime of S.P.S. is pretty high, it will not last forever. So, regular maintenance is very important to guarantee the S.P.S.’s reliability. How often maintenance should be done depends on the operating condition and temperature. The operating temperature will affect the frequency of return for repair, which is shown as below:
<table>
<thead>
<tr>
<th>Ambient Temperature</th>
<th>40°C ~ 45°C</th>
<th>Once per three years</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ambient Temperature</td>
<td>35°C ~ 40°C</td>
<td>Once per four years</td>
</tr>
<tr>
<td>Ambient Temperature</td>
<td>30°C ~ 35°C</td>
<td>Once per five years</td>
</tr>
</tbody>
</table>

The data above will vary depending on component grade used for the S.P.S. Please contact your local supplier for more information about the maintenance and repair services.

6.4 Load Capacity and Ambient Temperature

Internal temperature of the S.P.S. will vary depending on output load condition and efficiency. Reducing the output load will decrease the internal temperature and extend the S.P.S.’s lifetime.

(1) Ambient Test Condition
(a) Size of test chamber (internal volume): 45x45x50cm (WxDxH)
(b) $T_A$: Internal temperature of ambient tester (simulate S.P.S.’s external temperature)
(c) $T_{A1}$: The maximum internal temperature of the S.P.S. (simulate S.P.S.’s internal temperature)
(d) $T_{PC}$: The highest temperature on the case of the S.P.S.
(e) $T_{CAP}$: The maximum temperature on the electrolytic capacitor of the S.P.S.

Figure 6.3: Set up diagram in the chamber
(2) Free Air Convection Models (SP-100-24)

Figure 6.5: Relationship between load and temperature for free air convection models

Figure 6.4 Picture of ambient tester (chamber)
(3) Forced Airflow Models (SP-200-24)

![Graph of load vs temperature for two different temperatures (Ta=25° and Ta=50°).]

Figure 6.6: Relationship between load and temperature for forced airflow models

6.5 Reliability and Operating Environment

The operating environment of the S.P.S. will affect its reliability.

1) Vapor, Moisture

If the S.P.S. is used in vaporous or moisture rich environment, there’s the possibility that the S.P.S. may become out of order after a certain period of operation. Therefore don't use the S.P.S. in moisture rich environment. If it is necessary, please contact the supplier for more information about special treatment against the moisture.

2) Dust

If the S.P.S. is used in a dusty environment, the dust may collect on the fan and PCB causing circuit failure because of decay in the insulation. Protective measure should be taken to reduce dust settlement (e.g. dust filter).

3) Vibration and Impact

If the S.P.S. is used in a vibrating environment or subjected to impact, the power supply may become out of order.

4) Electromagnetic Field

If S.P.S is used in an environment with high electrical field, magnetic field, or strong electromagnetic wave, the power supply may become out of order.
6.6 MTBF (Mean Time Between Failure)

Mean Time between Failure is the expected value for reliability prediction. Estimating the reliability of the products under development or in mass production can help decide whether customers' needs are satisfied.

MTBF is the mean operating time until the reliability of the product goes down to 36.8%. For instance, if the product’s MTBF is 20,000 hours, it doesn't mean that this product can be used for 20,000 hours, but rather that after being used for 20,000 hours, the probability for proper operation is 36.8% (e^{-1}=0.368).

If it have been used for 2000 hours, the reliability at that moment is \( e^{-\frac{1}{10}} = 0.905 \)

If it have been used for 200 hours, the reliability at that moment is \( e^{-\frac{1}{100}} = 0.999 \)

\[
MTBF = \frac{1}{\lambda}
\]

\[
R(t) = e^{-\lambda t}
\]

\( R(t) \): Reliability

\( \lambda \): Failure Rate

\( t \): Working time

\( e \): 2.718

MTBF can be calculated by two different methods, which are “Part count” and “Stress Analysis”. The regulations, MIL-HDBK-217F Notice 2 and TELCORDIA SR/TR-332(Bell Code) are commonly used to calculate MTBF. MIL-HDBK-217F is a United States military standard, and TELCORDIA SR/TR-332(Bell Code) is a commercial regulation. Currently, Meanwell adapts MIL-HDBK-217F Notice 2 as the main calculation model.

1. **Parts Count Method**

   Use MIL-HDBK-217F to get the failure rate for all components in the product and combining all the failure rates to get the reliability value.

2. **Stress Analysis Method**

   Operating a product at normal condition and within rated specification, a list of components’ stress data can be gathered. Using the stress data in conjunction with the MIL-HDBK-217F standard, we can estimate reliability by the stress analysis method.
6.7 Reliability test procedure for MW product

Based on previous experiences, 70% of failures can be eliminated during the developing phase. Therefore, MW pays significant attention to any quality issues that may arise during development and production.

(1) D.R. (Design Review): executed by RD management
   (a) Circuit/ architecture: reviewing the stability of the applied technology and circuits. Furthermore, compare with similar circuit from other MW products.
   (b) New part selection and approval: review and verify the quality and specification of the selected new component. And also justifies the ability of the vendor to continuously supply the particular part in long term.
   (c) Cost Analysis: control the manufacturing cost of developing products to meet the marketing target
   (d) Ability to manufacture: review and adapt new equipment or manufacturing process in order to produce the new products.

(2) D.V.T. (Design Verification Test): executed by RD design verification department
   (a) ATE (Automatic Testing Equipment): QE engineers will prepare ATE test programs, and DVT engineers will test the power supply with the provided program.
   (b) Safety/EMC: base on the different safety requirement of the developing product, safety engineer will verify the design, and submit to safety agency for approval.
   (c) Component stress test: verify the electrical stresses on critical components. Those components have to be able to withstand the stresses during different operating conditions.

(3) D.Q.T. (Design Qualification Test): executed by QA department
   (a) Design Review: a. verifies electrical functions in worst case operation.
       b. BD/ high voltage resistor/ FAN quality/ life cycle of \( V_{cc} \) capacitor… review the selection of these components.
   (b) Environmental and Accelerated Life in combination with different conditions of temperature/ humidity/ output load/ AC input, to verify the reliability and functionally of the product when operating in different environments.
(c) Package-delivering Simulation: review the mechanical structure and material of the products by shaking and dropping the power supply as an individual unit or a set (carton).

Vibration testing conditions:
(1) Waveform: Sine Wave
(2) Frequency: 10 Hz ~ 500 Hz
(3) Sweep Time: 10 min/sweep cycle
(4) Acceleration: 2G ~ 5G
(5) Orientation: X.Y.Z
(6) Test Time: 1 hour in each axis
(7) Sample Condition: Single unit /1 Carton (Packed)

Drop Test:

Chapter 7
Notes On Operation

7.1 Input Fuse
Each S.P.S. has a built-in fuse for protection. Once the fuse is blown, it means that something is wrong inside the power supply. If the power supply can not operate properly after replacing with a fuse of the same type and rating, please send back to the supplier for repair. If you want to add an external fuse, be sure that the rating of this fuse should be less than or equal to the internal fuse.

7.2 Safety
Inside the S.P.S., there is high working voltage of 200~800V on the circuit. Therefore don't touch the components when the unit is powered ON or you may get shocked and endanger your life. When the S.P.S. is abnormal, please send it back to the supplier. "Please Don't Try To Fix It Yourself."

7.3 Grounding
Use short and thick wiring when connecting the frame ground (FG) of the S.P.S. to earth ground on the case of the equipment to assure safety and prevent noise and leakage current.
7.4 Input and Output Wiring

(1) Input and output should be wired in opposite directions to prevent input surge and output ripple noise from interfering with each other.

(2) Output wiring should be short, thick, and meet the output current rating. Also, adding a small capacitor at the load can effectively reduce the noise. (Please refer to section 2.8)

(3) Suitable terminal screws, wires, and tools should be used when connecting to the terminal block.

(4) The FG (Frame Ground) of the AC input is different from the ground (-V / COM) of the DC output. There may be some isolation capacitors between them or it may be shorted together sometimes.
7.5 Heat Dissipation

(1) Each power supply should be installed in places with proper ventilation. (Example: installed in places with good ventilation, or inside enclosures with ventilation opening at the top)

(2) Correct installation direction and location. (Example: ventilation holes face upward)

(3) Each power supply should have proper heat sink. (Example: if the S.P.S. uses case as its heat sink, be sure to connect the case tightly and flush to the system’s metal surface)

(4) When more than one power supply is operated at the same time, be sure that there is enough space between each power supply. (Keep 5~15cm of space depending on the magnitude of the output power.)

(5) Using forced airflow can effectively improve heat dispersing. (Example: add a fan and deploy it at the bottom of the system if using inhaling airflow. In contrast, deploy it at the top of the system if using exhaling airflow.)

![Figure 7.3: More than one power supply working at the same time, space for airflow should be taken into consideration](image)

7.6 Output Derating (Please refer to the spec. of each machine)

(1) Output-Temperature: We need to reduce the output power depending on the operating temperature and the direction that the S.P.S. is allocated.
Figure 7.4 Relationship between output power and temperature (derating curve)

Example: If the S.P.S. is vertically installed, output power can be 100% between 0 ~ 50°C, and between 50 ~60°C the output power should be derated. At 60°C we need to reduce the output power to 60% of load. Above 60°C, we can not guarantee proper operation and lifetime of the unit.

(2) Output Power to Input Voltage

Figure 7.5 Relationship between output power and input voltage

When the input voltage is low, S.P.S. will have higher power loss because of the PFC circuit, therefore we need to reduce the output power. Refer to figure 7.5, between 110V ~ 264V the S.P.S. can output full load, but between 90V~110V we need to reduce the output power. At 90V, the output power will be derated to 80% of full load.
7.7 Remote ON/OFF Switch and Remote Sensing Wiring

(1) Remote ON/OFF Switch: Using a TTL control signal connected to the +RC, -RC terminals of the S.P.S., we can control the output of the power supply. When +RC and -RC is short (0V), the S.P.S. will be ON; when it is open (the voltage between the two terminals > 4V), the S.P.S. is turned OFF. However, some models use different control logic.

(2) Remote Sensing: We can compensate output line voltage drop by connecting +S and -S terminals to the load, but wires with enough diameter should still be used. In general this function can compensate for a voltage drop up to 0.3 ~ 0.5V. (About wire voltage drop/current, please refer to the appendix.)

7.8 Operation in Parallel

When power supplies are connected in parallel, we can increase the output current or use them for the redundant (back-up) function. Be sure that the tolerance of output voltage and wiring impedance are very small when connecting in parallel.

(1) S.P.S. With Built-in Parallel Function: Connecting “P” terminals together such as the PSP models (“G” terminal also need to be connected together). Input/output should be connected in parallel first and then connect to the AC source/load just as figure 7.7 (some S.P.S. need a minimum load after paralleling).
Notes on parallel operation:
1. Output voltage tolerance should be as small as possible (tolerance < 2%).
2. The power supplies should be paralleled using short and large diameter wiring and then connected to the load.
3. After paralleling, the available output power would be around 90% of the total power.
4. When power supplies are paralleled, if the total load is lower than 10% load of the individual unit, the indicator light and signal function (Power Good, Pok, Alarm Signal) may malfunction.
5. To make sure that the load current is effectively shared in parallel operation, in general we limit 4-6 power supplies to be paralleled at one time.
6. In some models, we also need to parallel the +S, -S terminals of the control connector to reduce unstable pulsation of output voltage.

(2) S.P.S. Without Built-in Parallel function (general models)
1. Add a diode at the positive-output of each power supply (as figure 7.8), the current rating of the diode should be larger than the maximum output current rating and attached to a suitable heat sink. This is only for redundant use (increase the reliability of the system) and users have to check suitability of the circuit by themselves.
2. Add a small series resistor about 0.1Ω on the positive-output side of each power supply. This is only good for small-output-current models and also need to consider the power loss and heat problems of the resistor. Users have to check suitability of the circuit by themselves. This is generally suitable for models with small output current.

3. When using S.P.S. in parallel connection, the leakage current will increase at the same time. This could pose as a shock hazard for the user. So please contact the supplier if you have this kind of application.

**7.9 Operation in Series**

Power supplies can be operated in series. Here are the methods of doing it:
(1) Positive and negative terminals are connected as figure 7.10:

![Diagram of positive and negative terminals connected in series](image)

**Figure 7.10**: Positive and negative terminals connect in series

(2) Increase the output voltage (current does not change). If there is no reverse blocking diode in the power supply, we should add an external blocking diode to prevent the damage of power supply while starting up. The voltage rating of the external diode should be larger than $V_1+V_2$ (as figure 7.11).

![Diagram of series connection by adding external reverse blocking diodes](image)

**Figure 7.11**: Series connection by adding external reverse blocking diodes

### 7.10 Output Wiring for Smaller Loads

When using one S.P.S. to power two different loads, a fuse should be added to the wiring of the smaller load for protection. If a short-circuit condition occur, this fuse can protect the wiring from being burned out.

![Diagram of output wiring](image)

**Figure 7.12** Output wiring
7.11 Minimum Load Requirement

To assure the regulation and stability of auxiliary outputs (CH2~CH4) on a multi-output S.P.S., we need to add a minimum load on the main channel (CH1). For example: Spec. of D-120 is 5V/6A, 24V/4A. When the output is 5V/0A, 24V/4A, the 24V output voltage will be lower than the spec. In this situation, if we add a minimum load of 1A (by paralleling a $5\Omega/10W$ resistor) at the 5V channel, then the output voltage of the 24V channel would increase to the tolerance range of the spec. Users also need to add a minimum load at the 24V channel to keep the output voltage within the spec. if only the 5V channel is used during certain modes of operation.

7.12 Operation in Low Temperature

If the S.P.S. uses a thermistor to suppress the inrush current; it could cause a failure to start up at low temperature (such as $-10^\circ$C) due to temperature sensitivity. Following are some methods to solve this problem:

1. Keep the power supply at standby status (Keep AC source ON and then switch the output ON/OFF).
2. Use heater to increase the ambient temperature of S.P.S.
3. Reduce output load.

If the working temperature on the spec is $-10^\circ$C~ $50^\circ$C and we want to operate it at $-20^\circ$C, we should pay attention to the following issues:

1. Relative humidity should be low to prevent ice formation.
2. The output ripple will be larger.
3. Since we usually use the thermistor as the inrush current suppresser and the thermistor will increase its resistance when the temperature goes down. It is possible that the power supply may take a long time to start up or there could be failure to power up.
4. We can not guarantee the extent of reduction in functionality when the S.P.S. is working out of the specification range.
7.13 Working in High Temperature or In a Environment with Huge Temperature Difference

There are high voltage and high impedance circuits in the S.P.S. So before turning on the power supply, be sure that there is no water condensation in the unit. If the S.P.S. is working at low temperature and then stored at high temperature or outdoor environment with high moisture and temperature differences between day and night, water may condense in the power supply and damage it. If necessary, please contact the supplier about providing anti-moisture treatment.

7.14 Special Load

(1) Capacitive Load

If the S.P.S is connected to a large capacitive load such as large capacitors or lighting device, the set up time of the S.P.S. will increase or may even prevent the S.P.S. from starting up. Users should use power supplies with the constant current limiting function or ask the supplier for assistance.

(2) Inductive Load

If the S.P.S is connected in parallel with coil loads, such as motors, solenoid valves etc., there will be a huge peak current or a reverse voltage when the load is activated. It is recommended to use suitable capacitors and add a blocking diode to protect the S.P.S. We also can use S.P.S. with the constant current limiting function to deal with it.

(3) Dynamic Load

If the S.P.S. is connected to a dynamic load such as LED monitor, the output current will change abruptly and cause high ripple current and audio noises. We can add suitable capacitors at the load end to improve these problems (but be careful about delay problem while turning ON).

7.15 Charger Operation (To assure charging efficiency and lifetime, please use models with charging function.)

When the S.P.S. is used as a charger, be sure to add a series blocking diode at the output terminal (with suitable heat sink). This arrangement is to prevent reverse voltage from the battery which may damage the SPS. Inappropriate operation can easily damage the S.P.S. or batteries, please contact the supplier if you have any questions about this type of application.
7.16 Inrush Current Suppressing Circuit

When using many S.P.S. at the same time, the huge inrush current may exceed the rating of external wiring. The following delay circuit can suppress the inrush current caused by multi-S.P.S. operation.

![Delay Circuit Diagram](image1)

Figure 7.13: Delay circuit

7.17 Input Surge and Shock Suppression

(1) Input Surge: The ON/OFF of heavy industrial machine will cause variance of nearby power line voltage. Sometimes the variance is so large that specification of the S.P.S. is exceeded and in turn may damage it, so there is a “surge absorber” between AC/L and AC/N in the S.P.S. to absorb this abrupt high voltage.

(2) Shock Suppression: Lightning shock is a type of short-term high voltage and high energy pulse. To prevent damage from shock, we should add surge absorbers between AC/L - AC/N, AC/L - FG, and AC/N - FG, which are shown in figure 7.14.

![Surge Absorber Diagram](image2)

Figure 7.14: The connection of the Surge Absorber
7.18 Output Ripple Noise Suppression

(1) Differential-Mode Noise Suppression
As in figure 7.15, adding C1~C4 can reduce this form of noise. C1 and C3 are electrolytic capacitors (reference value: 47uF~100uF), while C2 and C4 are high frequency capacitors (reference value: 0.01uF~0.1uF). In general, adding C3 and C4 is good enough to reduce this noise.

(2) Common-Mode Noise Suppression
As in figure 7.15, adding L1, C5, and C6 can reduce the common mode noise. C5 and C6 are high frequency capacitors.

![Figure 7.15: Ripple noise suppression](image)

7.19 Trimming Output Voltage via External Resistor or Voltage
Some models can reach a desired output voltage by trimming through an external resistor or external voltage (Example: 1~5VDC).

(1) Trimming Output Voltage through External Resistor

![Figure 7.16: The diagram for using external resistor](image)

![Figure 7.17: Dependence of output voltage on value of external resistor](image)
(2). Trimming Output Voltage through External Voltage

Figure 7.18: The diagram for using external voltage

Figure 7.19: Dependence of output voltage on value of external voltage

Notes:
1. The range of trimming voltage through external resistor or voltage control varies from model to model. Please refer to the specification before using it.
2. If you are not going to use the trim function (via voltage control), please connect its pins in short circuit. Otherwise, the power supply may malfunction. For more details, please consult the specification.
Chapter 8

Technical Support Q & A

This chapter consists of some of the most frequently asked questions. Due to limited number of pages available, further updates will only be done on the Mean Well website (www.meanwell.com). Please look to the FAQ section on the MW site for future updates.

8.1 Notes on choosing a switching power supply?
Ans: (1) To increase the reliability of the S.P.S., we suggest users choose a unit that has a rating of 30% more power than actual need. For example, if the system needs a 100W source, we suggest that users choose a S.P.S. with 130W of output power or more. By doing this, you can effectively boost the reliability of the S.P.S. in your system.
(2) We also need to consider about ambient temperature of the S.P.S. and whether there is additional device for dissipating the heat. If the S.P.S. is working in a high temperature environment, we need to make some derating to the output power. The derating curve of “ambient temperature” versus “output power” can be found on our spec sheets.
(3) Choosing functions based on your application:
   A. Protection function: Over Voltage Protection (OVP), Over Temperature Protection (OVP), Over Load Protection (OLP), and etc.
   B. Application function: Signaling Function (Power Good, Power Fail), Remote Control, Remote Sensing, and etc.
   C. Special function: Power Factor Correction (PFC), Uninterruptible Power Supply (UPS) function.
(4) Make sure that the model qualifies for the safety standards and EMC regulations you need.

### 8.2 How do we choose a power supply to charge a battery?

**Ans:** MEAN WELL has ESC, SC, PA, PB series for battery charger purpose (120~360W). If these series does not meet customers’ demands and they like to choose a power supply as a charger, we advice to pick up one which over load protection (OLP) mode is constant current limiting. The models in this mode provide constant current even when the protection circuit is triggered.

The second choice is fold-back current limiting or constant wattage model. In this model, when a battery is running low, the output current of the power supply will gently increase. The level of increase depends on battery’s capacity and degree of exhaustion.

Hiccup or shut down model are not recommended because it will stop to generate current when OLP happens.

### 8.3 Can MEAN WELL's power supply be used in the range of 45Hz ~ 440Hz? If YES, what will happen?

**Ans:** MEAN WELL’s power supply can be used within this frequency range. But if the frequency is too low; the efficiency will also be lower. For example, when a SP-200-24 is operated under 230VAC and rated load, if the frequency of AC input is 60 Hz, the efficiency is around 84%; however, if the frequency of AC input reduces to 50 Hz, the efficiency will be around 83.8%. If the frequency is too high, the power factor of the S.P.S. with PFC (power factor correction) function will reduce and this also will cause higher leakage current. For example, when a SP-200-24 is operated under 230VAC and rated load, if the frequency of AC input is 60 Hz, the power factor is 0.93 and the leakage current is around 0.7mA; however, if the frequency of AC input increase to 440 Hz, the power factor will decrease to 0.75 and the leakage current will rise to around 4.3mA.

### 8.4 If we need a 24V output power supply, but MEANWELL does not have this model, can we use two 12V power supplies connecting in series instead of one 24V power supply?

**Ans:** YES, basically you can do this to get the right output voltage, but be careful that the rated output current of the series system should be the rating of the minimum one in these series connected power supplies. Furthermore, we like you to parallel a diode at the output of power supply to prevent possible damage of internal capacitors.
8.5 If we need a 600W output, can we use two units of S-320 connected in parallel?

Ans: No, you can not do this connection because S-320 is not equipped with the parallel function. When two power supplies are connected in parallel, the one with higher output voltage will share more loading and deliver more (even “all”) power to the load and cause these two power supplies to be unbalanced. We suggest using PSP-300 or PSP-500 because it is equipped with the current sharing function.

8.6 When testing a dual output power supply, the +5V channel is correct, but the +12V channel is over the specification. What is going on?

Ans: There are some minimum-load requirements on MEAN WELL’s multi-output power supplies, please refer to the specification first before connecting the load. When the load condition is 5V/4A, 12V/0A, the output voltage of the 12V channel will be around 12.8V that is over the ±6% of voltage deviation (12.72V) specified in the spec. sheet. If we add in the minimum load 0.2A to the 12V channel, the 12V channel will reduce to around 12.3V which is within the specification.

8.7 Why I can not turn on the power supply smoothly when the loads are motors, light bulbs or capacitive loads?

Ans: If you connect the S.P.S. to motors, light bulbs, or high capacitive loads, you will have a high output surge current when you turn on the S.P.S. and this high surge current will cause failure of start up. We suggest using S.P.S. with constant current limiting protection to deal with these loads.

8.8 Why did the power supply shuts down during operation and after turning it off, I can restart the power supply again?

Ans: In general there are two circumstances that will cause the power supply to shut down. The first one is the activation of the over-load-protection (OLP). To deal with this situation, we suggest increasing the rating of the output power or modifying the OLP point. The second one is the activation of over-temperature protection (OTP) when the internal temperature reaches the pre-set value. All of these conditions will let the S.P.S. enter protection mode and shut down. After these conditions are removed, the S.P.S. will be back to normal.
8.9 The output ground (GND) and frame ground (FG) is the same point in my system, can MEAN WELL’s power supplies be used in such system?

Ans: Yes. Since our products are designed based on isolation concept, it will be no problem that the output ground (GND) and frame ground (FG) is the same point in your system. But, EMI may be affect by this connection.

8.10 During the operation of MEAN WELL power supply, there is some leakage current on the case. Is this normal? Will this leakage current hurt human body?

Ans: Due to the requirement of EMI, there will be some Y capacitors between line and neutral to the FG (case) to improve EMC. These Y capacitors will cause some leakage current flow from line or neutral to the case (normally case will be connected to earth ground). For example, IEC-60950-1 requires that this current should be less than 3.5mA for IT equipment, so basically the leakage current you find on the case will not hurt human body. Proper connection to Earth ground will solve the leakage current problem.

8.11 For certain need, is it possible to reduce the noise of fan?

Ans: Noise is directly related to the fan which is build into the power supply. Lowering the airflow of the fan means reducing the heat dissipation ability. It will also influence the reliability of the products. Furthermore, minimum airflow of fans is defined by Safety Organization and a safety appendage will be needed if using a new fan. Generally, when we choose a suitable power supply, fan is not necessary if wattage is under 150W. Between 150~500W, both fan and fan less products are available. Above 500W, a fan is needed.

8.12 What should be noticed when installing a power supply in vertical and horizontal directions?

Ans: Most small wattage and fan less power supplies are mainly installed in the horizontal position. If you have to install it vertically because of mechanical limitation, you should consider the output derating due to the heat concern. The temperature derating curve can be found on the spec sheet. Regarding the power supplies with built-in fan or the application has forced cooling system, vertical and horizontal installations have less difference.
Ex. In SP-150 derating curve, the ambient temperature difference in application is 5 Celsius from vertical to horizontal. The output wattage in forced cooling can be 20% higher than air cooling convection.

8.13 Why the fan is not running after turning on certain models?
Ans: Some models control the fan based on internal temperature to extend its life time. For example, the Fan ON temperature for the S-240 series is $\geq 40^\circ$C (RT1). If the internal temperature does not reach the preset value, the fan will remain still until receiving the start up signal.

8.14 What is “Inrush Current”? What will we notice?
Ans: At input side, there will be (1/2 ~1 cycle, ex. 1/120 ~ 1/60 seconds for 60 Hz AC source) large pulse current (20~60A based on the design of S.P.S.) at the moment of power on and then back to normal rating. This “Inrush Current” will appear every time you turn on the power. Although it will not damage the power supply, we suggest not turning the power supply ON/OFF very quickly within a short time. Besides, if there are several power supplies turning on at the same time, the dispatching system of AC source may shut off and go into protection mode because of the huge inrush current. It is suggested that these power supplies start up one by one or use the remote control function of S.P.S. to turn them on/off.
8.15 What is PFC?
Ans: PFC stands for Power Factor Correction. The purpose of PFC is to improve the ratio of apparent power and real power. The power factor is only 0.4~0.6 in non-PFC models. In PFC models, the power factor can reach above 0.95. The calculation formulas are as below:
- Apparent Power=Input Voltage x Input Current (VA)
- Real Power= Input Voltage x Input Current x Power Factor (W)

From the environment friendly point, the electric power plant needs to generate a power which is higher than apparent power in order to steadily provide electricity to the market. The real usage of electricity should be defined by real power. Assuming the power factor is 0.5, the power plant needs to produce more than 2VA to satisfy 1W real power. On the contrary, if the power factor is 0.95, the power plant only needs to generate more than 1.06VA to provide 1W real power need. It will be more effective.

8.16 What is the difference between –V and COM which are marked on the output side?
Ans: COM (COMMON) means common ground. Please see below:
- Single output: Positive pole (+V), Negative pole (-V)
- Multiple output (Common ground): Positive pole (+V1, +V2…), Negative pole (COM)

8.17 In MEAN WELL's catalog, we see AC and DC at input, what is it all about?
Ans: Due to different circuit designs, MEAN WELL power supply inputs consists of three types as below:(√2VAC≒VDC)
- a. 85~264VAC;120~370VDC
- b. 176~264VAC;250~370VDC
- c. 85~132VAC/176~264VAC by Switch; 250~370VDC

(1) In a and b inputs models, power supply can work properly no matter under AC or DC input. Some models need correct connection of input poles, positive pole connects to AC/L; negative pole connects to AC/N. Others may require opposite connection, positive pole to AC/N; negative pole to AC/L. If customers make a wrong connection, the power supply will not be broken. You can just reverse the input poles and power supply will still work.

(2) In c input models, please make sure that you switch the 115/230V input correctly. If the switch is on the 115V side and the real input is 230V, the power supply will be damaged.
8.18 Why the input voltage marked on the spec. sheet is 88~264 VAC while the label on the power supply says that it is 100~240VAC?
Ans: During safety verification process, the agency will use a stricter standard -- ±10% (IEC60950 uses +6%, -10%) of the input voltage range labeled on the power supply to conduct the test. So, operating at the wider input voltage range as specified on the spec. sheet should be fine. The narrower range of input voltage labeled on the power supply is to fulfill the test standard of safety regulation and make sure that users insert input voltage correctly.

8.19 Will MeanWell’s products with CE marking meet the EMC requirements after assembling into my system?
Ans: We cannot guarantee 100% that the final system can still meet the EMC requirements. The location, wiring and grounding of the switching power supply in the system may influence its EMC characteristics. In different environment or applications, the same switching power supply may have different outcomes. Our test results are based on setup shown in the EMC report.

8.20 What is different between information (EN60950-1) and medical (EN60601-1) safety standard?
Ans: According to safety standard, the leakage current in EN60950-1 Class I cannot exceed 3.5mA; in EN60601-1 cannot exceed 0.3mA. Others criteria like safe distance and numbers of fuse are also different. Please consult the diagram below:

8.21 What is MTBF? Is it distinct from Life Cycle?

Ans: MTBF and Life Cycle are both indicators of reliability. MEAN WELL uses MIL-HDBK-217F as the core of MTBF. An expected reliability is forecasted through accounting component’s number (exclude fans). The exact meaning of MTBF is after continuously using of power supply in a certain time, the probability of operating properly is 36.8% (e^−1=0.368). If power supply is continuously used at double the MTBF time, the probability of operating properly becomes 13.5% (e^−2=0.135).

Life Cycle is found through using the temperature rise of electrolytic capacitor to estimate the approximate life of power supply. For example, SP-750-12 MTBF=769.3K hours; electrolytic capacitor C108 Life Cycle=202.2K hours (Ta=45°C).
Chapter 9
Failure Correction Notes

When the S.P.S. cannot function properly, please refer to the following checklist and failure correction notes in table 9.1 and 9.2. If it still cannot be fixed after each item had been checked, some internal components might be broken. Please contact the supplier for repair service.

### 9.1 Notes on Returning SPS for Repair

1. Please attach a small note along with the defective products that shortly describes the situation of failure. This will help us to make the failure analysis.
2. Please tighten the screws on terminal block. (You do not have to send back accessories and AC cord.)
3. Please return defective units in suitable packages to prevent damage during transportation, especially for the open frame models which have SMD components.
4. There will be a repair charges for products which warranties are one year overdue. The amount of repair charges depends on models’ prices and defective situations.
5. We suggest that you replace with a new unit if the broken power supply had been used for more than five years.
6. After receiving the defective products, we will finish the repair process within 3 working days and send it back within 5 working days.
7. As to the failure analysis, please refer to the tag hanging on the power supply.
8. If you need more details about your repair items, please contact your sales representative.

**TEL:** 02-2299-6100 Ext 173 or 177

### 9.2 Recognizing the Serial Number

<table>
<thead>
<tr>
<th>R</th>
<th>A0</th>
<th>0</th>
<th>000001</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>
(a) The first part of number denotes
C. Product Number (Made in Taiwan)
D. Product Number (Made in China)
R. Product which complies with RoHS (Made in Taiwan)
(b) The second part of number denotes the year of manufacturing
Example: 99 means 1999; A6 means 2006
(c) The third part of number denotes the month of manufacturing. A means
November; B means December.
(d) The fourth part of number denotes the exact order number when this model is
being made. Example: 000001 means it is the first model made in this series.

9.3 Statistics for Repair
We set the target that the 2-year repair rate (the percentage that the products returned
within 2 years after shipping out) should decrease 10% every year. Based on previous
records, the rate was 0.058% in 2004 and 0.056% in 2005. The failure rate has steadily
decreased each year. We are looking forward to pushing this rate under 0.05% in 2006.

Calculation Formula of Failure Rate under Warranty

\[
\text{Failure Rate under Warranty} = \frac{\text{Accumulation of the failure number annually}}{\text{Total sales number annually}}
\]

Example: In 2005
Failure Rate under Warranty = \( \frac{2337}{4132256} = 0.056\% \)
Appendix A. Explanation Of Electrical Glossaries

**Abnormal Failure:**
An artificially induced failure of a component, usually as a result of "abnormal" testing for regulatory agency safety compliance.

**AC (Alternating Current):**
A periodic current the average value of which over a period is zero. Unless distinctly specified otherwise, the term refers to a current which reverses at regularly recurring intervals of time and which has alternately positive and negative values.

**AC Line:**
The set of conductors that route ac voltage from one point to another.

**AC Line Filter:**
A circuit filter placed in the ac line to condition or smooth out variations that are higher in frequency than the line frequency.

**Ambient Temperature:**
The temperature of the environment, usually the still air in the immediate proximity of the power supply.

**Ampere:**
(A) Electron or current flow representing the flow of one coulomb per second past a given point in a circuit.

**Amplifier:**
A circuit or element that provides gain.

**Anode:**
The electrode from which the forward current flows within the cell.

**ANSI:**
American National Standards Institute.

**Apparent Power:**
A value of power for AC circuits that is calculated as the product of RMS current times RMS voltage, without taking the power factor into account.

**Asymmetrical Waveform:**
A current or voltage waveform that has unequal excursions above and below the horizontal axis.

**ATE:**
Automatic Tester Equipment.

**Attenuation:**
Decrease in amplitude or intensity of a signal.
**Auxiliary Power:**
A power source supplying power other than load power as required for proper functioning of a device.

**Bandwidth:**
A range of frequencies over which a certain phenomenon is to be considered.

**Bead:**
A small ferrite normally used as a high frequency inductor core.

**Bifilar Winding:**
Two conductors wound in parallel.

**Bipolar Transistor:**
A transistor which operates by the action of minority carriers across a P/N junction; and is a current controlled device as opposed to a voltage controlled device.

**Bleeder Resistor:**
A resistor added to a circuit for the purpose of providing a small current drain, usually to provide a load for improving output voltage stability, or to assure discharge of capacitors.

**Bobbin:**
A device upon which the windings of a transformer or inductor are wound, which provides a form for the coil and insulates the windings from the core.

**Breakdown Voltage:**
A voltage level at which dielectric insulation fails by excessive leakage current or arcing. In reference to power supplies the breakdown voltage is the maximum AC or DC voltage that can be applied from input to output and/or chassis.

**Bridge Converter:**
A DC to DC converter topology (configuration) employing four active switching components in a bridge configuration across a power transformer.

**Bridge Rectifier:**
A full wave rectifier circuit employing four rectifiers in a bridge configuration.

**Brownout:**
A reduction of the AC mains' distribution voltage, usually caused deliberately by the utility company to reduce power consumption when demand exceeds generation or distribution capacity.

**Brownout Protection:**
The ability of a power supply to continue operating within specification through the duration of a brownout.
Burn-In:
Operating a newly manufactured power supply, usually at rated load, for a period of time in order to force component infant mortality failures or other latent defects before the unit is delivered to a customer.

Capacitance:
Inherent property of an electric circuit or device that opposes change in voltage. Property of circuit whereby energy may be stored in an electrostatic field.

Capacitive Coupling:
Coupling of a signal between two circuits, due to discrete or parasitic capacitance between the circuits.

Cathode:
The electrode from which the forward current flows out the cell.

Center Tap:
An electrical connection made at the center of a transformer or inductor winding, usually so as to result in an equal number of turns on either side of the tap.

Chassis:
The structure supporting or enclosing the power supply.

Chassis Ground:
The voltage potential of the chassis.

Choke Coil:
An inductor.

Circular Mil:
Cross-sectional area of a conductor one mil in diameter.

Common Mode Noise:
Noise present equally on two conductors with respect to some reference point; often used specifically to refer to noise present on both the hot and neutral AC lines with respect to ground.

Compensation:
The addition of circuit elements to assist in stabilization of a control loop.

Constant Current Power Supply:
A power supply designed to regulate the output current for changes in line, load, ambient temperature, and drift resulting from time.

Constant Voltage Power Supply:
A power supply designed to regulate the output voltage for changes in line, load, ambient temperature, and drift resulting from time.
Control Circuit:
A circuit in a closed-loop system, typically containing an error amplifier, which controls the operation of the system to achieve regulation.

Convection:
The transfer of thermal energy in a gas or liquid by currents resulting from unequal temperatures.

Converter:
An electrical circuit which accepts a DC input and generates a DC output of a different voltage, usually achieved by high frequency switching action employing inductive and capacitive filter elements.

Cooling:
Removal of heat, which, in a power supply, is generated by transformation, rectification, regulation, and filtering. It can be accomplished using radiation, convection, forced air, or liquid means.

Cross Regulation:
The effect of a load change on one output to the regulation of another output.

Crowbar:
An over-voltage protection method which shorts the power supply output to ground in order to protect the load when an over-voltage fault is detected.

Current Limiting:
An overload protection circuit that limits the maximum output current of a power supply in order to protect the load and/or the power supply.

Current Mode:
A control method for switch-mode converters where the converter adjusts its regulating pulse width in response to measured output current and output voltage, using a dual loop control circuit. Since output current is measured, current mode control allows accurate sharing between power supplies.

DC-DC Converter:
A circuit or device that changes a dc input signal value to a different dc output signal value.

Derating:
A reduction in an operating specification to improve reliability. For power supplies it is usually a specified reduction in output power to facilitate operation at higher temperatures.

Design Life:
The expected lifetime of a power supply during which it will operate to its published specifications.
**Differential Mode Noise:**
Noise that is measured between two lines with respect to a common reference point excluding common-mode noise. The resultant measurement is the difference of the noise components of the two lines. The noise between the DC output and DC return is usually measured in power supplies.

**Direct Current (DC):**
Current that the polarity doesn’t change with respect to time.

**Drift:**
The change in an output voltage, after a warm-up period, as a function of time when all other variables such as a line, load, and operating temperature are held constant.

**Dropout:**
The lower limit of the AC input voltage where the power supply just begins to experience insufficient input to maintain regulation. The dropout voltage for linear supplies is quite load dependent. For most switching supplies it is largely design dependent, and to a smaller degree load dependent.

**Duty Cycle:**
The ratio of time on to time off in a recurring event.

**Dynamic Load:**
A load that rapidly changes from one level to another. To be properly specified, both the total change and the rate of change must be stated.

**Efficiency:**
The ratio of total output power to input power expressed as a percentage. Normally specified at full load and nominal input voltage.

**Electronic Load:**
An electronic device designed to provide a load to the outputs of a power supply, usually capable of dynamic loading, and frequently programmable or computer controlled.

**EMI:**
Abbreviation for Electromagnetic Interference, which is the generation of unwanted noise during the operation of a power supply or other electrical or electronic equipment.

**ESR:**
Equivalent Series Resistance. The value of resistance in series with an ideal capacitor which duplicates the performance characteristics of a real capacitor.

**Fault Mode Input Current:**
The input current to a power supply with a short circuit on the output.
**FET:**
Field Effect Transistor, a majority carrier voltage controlled transistor.

**Filter:**
A frequency-sensitive network that attenuates unwanted noise and ripple components of a rectified output.

**Floating Output:**
An output of a power supply that is not connected or referenced to any other output, usually denotes full galvanic isolation. They generally can be used as either positive or negative outputs. Non-floating outputs share a common return line, and are hence DC referenced to one another.

**Flyback Converter:**
The flyback converter is the simplest type of switcher. In most cases, it uses one switch and only needs one magnetic element - the transformer.

**Foldback Current Limiting:**
A type of protection circuit where the output current decreases as the overload increases. The output current reaches a minimum as the load approaches a short-circuit condition.

**Forced Convention Cooling:**
Using outer sources (such as fans) to help hot components disperse the heat.

**Forward Converter:**
Similar to flyback converter but the forward converter stores energy in the output inductor instead of the transformer.

**Frequency:**
Number of cycles per second measured in “Hertz”.

**Full Bridge Converter:**
The full bridge is more complex than other switcher topologies. It has the capability for very high performance. It can product high power with four switchers and requires only two magnetic elements.

**Fuse:**
Safety protective device that permanently opens an electric circuit when overloaded.

**Ground:**
An electrical connection to earth or some other conductor that is connected to earth. Sometimes the term "ground" is used in place of "common," but such usage is not correct unless the connection is also connected to earth.
**Ground Loop:**
An unintentionally induced feedback loop caused by two or more circuits sharing a common electrical ground.

**Half-Bridge Converter:**
A switching power supply design in which two power switching devices are used to drive the transformer’s primary side.

**Heat Sink:**
Device used to conduct away and disperse the heat generated by electronic components.

**High Line:**
Highest specified input operating voltage.

**Hi-Pot:**
Abbreviation for High Potential, and generally refers to the high voltages used to test dielectric withstand capability for regulatory agency electrical safety requirements.

**Hold-Up Time:**
The length of time a power supply can operate in regulation after failure of the AC input.

**Input Line Filter:**
An internally or externally mounted low-pass or band-reject filter at the power supply input which reduces the noise fed into the power supply.

**Input Voltage Range:**
The range of input voltage values for which a power supply or device operates within specified limits.

**Inrush Current:**
The peak current flowing into a power supply the instant AC power is applied. This peak is usually much higher than the steady state input current due to the charging of the input filter capacitors.

**Inrush Current Limiting:**
A circuit that limits the amount of inrush current when a power supply is turned on.

**Insulation:**
Non-conductive materials used to separate electric circuits.

**Insulation Resistance:**
The resistance offered, usually measured in mega-ohms, by an insulating material to the flow of current resulting from an impressed dc voltage.

**Inverter:**
A power supply that produces an AC output, usually from a DC input.
Isolation:
Two circuits that are completely electrically separated with respect to DC potentials, and almost always also AC potentials. In power supplies, it is defined as the electrical separation of the input and output via the transformer.

Isolation Transformer:
A component that isolates the primary and secondary side in the switching power supply.

Isolation Voltage:
The maximum AC or DC voltage which maybe continuously applied from input to output and/or chassis of a power supply.

Layer Winding:
A transformer winding technique where the primary and secondary windings are wound over each other and separated by an insulation layer.

Leakage Current:
A term relating to current flowing between the AC supply wires and earth ground. The term does not necessarily denote a fault condition. In power supplies, leakage current usually refers to the 60 Hertz current which flows through the EMI filter capacitors which are connected between the AC lines and ground (Y caps).

Line Regulation:
The change in output voltage when the AC input voltage is changed from minimum to maximum specified. It is usually a small value, and may be near zero with current mode control.

Linear Regulator:
A regulating technique where a dissipative active device such as a transistor is placed in series with a power supply output to regulate the output voltage.

Load Regulation:
The change in output voltage when the load on the output is changed.

Local Sensing:
Using the voltage output terminals of the power supply as sense points for voltage regulation.

Logic Enable:
The ability to turn a power supply on and off with a TTL signal. A logic-low generally turns the supply off while a logic-high turns it on.

Long Term Stability:
Power supply output voltage change due to time with all other factors held constant. This is expressed in percent and is a function of component aging.
Magnetic Amplifier:
Sometimes abbreviated "Mag Amp," a saturating inductor that is placed in series with a power supply output for regulation purposes.

Mains:
The utility AC power distribution wires.

Margining:
Adjusting a power supply output voltage up or down from its minimal setting in order to verify system performance margin with respect to supply voltage. This is usually done electrically by a system-generated control signal.

Minimum Load:
The minimum load current/power that must be drawn from the power supply in order for the supply to meet its performance specifications. Less frequently, a minimum load is required to prevent the power from failing.

Modular:
A physically descriptive term used to describe a power supply made up of a number of separate subsections, such as an input module, power module, or filter module. Modular construction tends to lower the MTBF.

MTBF:
Mean Time Between Failures.

Noise:
Noise is the aperiodic, random component of undesired deviations in output voltage. Usually specified in combination with ripple.

Normal Value:
A usual, average, normal, or expected operating condition. This stated value will probably not be equal to the value actually measured.

Off Line:
A power supply which receives its input power from the AC line, without using a 50/60 Hz power transformer prior to rectification and filtering, hence the term "off line" power supply.

Open Frame:
A power supply where there is no external metal chassis; the power supply is provided to the end user essentially as a printed circuit board which provides mechanical support as well as supporting the components and making electrical connections.

Optoisolator:
An electro-optical device which transmits a signal across a DC isolation boundary.
**Output Good**
A power supply status signal which indicates that the output voltage is within a certain tolerance. An output which is either too high or too low will deactivate the Output Good signal.

**Output Impedance**
The ratio of change in output voltage to change in load current.

**Output Noise**
The AC component that may be present on the DC output of a power supply. Switch-mode power supply output noise has two components: a lower frequency component at the switching frequency of the converter and a high frequency component due to fast edges of the converter switching transitions. Noise should always be measured directly at the output terminals with a scope probe having an extremely short grounding lead.

**Overload Protection**
A power supply protection circuit that limits the output current under overload conditions.

**Overshoot**
A transient output voltage change which exceeds the high limit of the voltage accuracy specification and is caused by turning the power supply on or off, or abruptly changing line or load conditions.

**Overtemp Warning**
A TTL compatible signal which indicates that an over-temperature condition exists in the power supply. Most commercial power supplies are designed to shut down if an over-temperature condition exists.

**Over Voltage Protection**
A circuit which either shuts down the power supply or crowbars the output in the event of an over-voltage condition.

**Parallel Operation**
Connecting the outputs of two or more power supplies with the same output voltage for the purpose of obtaining a higher output current. This requires power supplies specially designed for load sharing.

**Peak Power**
The absolute maximum output power that a power supply can produce without immediate damage. Peak power capability is typically well beyond the continuous reliable output power capability and should only be used infrequently.
**Power Factor:**
The ratio of true power to apparent power in an AC circuit. In power conversion technology, power factor is used in conjunction with describing the AC input current to the power supply.

**Power Fail:**
A power supply interface signal which gives a warning that the input voltage will no longer sustain full power regulated output.

**Preload:**
A small amount of current drawn from a power supply to stabilize its operation. Preloads are usually provided by a bleeder resistor.

**Primary:**
The input section of an isolated power supply that is connected to the AC mains and hence has dangerous voltage levels present.

**Pulse Width Modulation (PWM):**
A switching power conversion technique where the on-line (or width) of a duty cycle is modulated to control power transfer for regulating power supply outputs.

**Push-Pull Converter:**
A switching-mode power supply topology which utilizes a center-tapped transformer and two power switches. The two switches are alternately driven on and off.

**Quasi Regulated Output:**
The regulation of an auxiliary output that is accomplished by regulation of the main output. A transformer turns ratio, commensurate with the desired auxiliary output voltage, is used in conjunction with the output around which the main control loop is closed. Quasi regulated outputs can be reasonably well regulated, but are significantly affected by second order effects in the converter.

**Rated Output Current:**
The maximum load current that a power supply can provide at a specified ambient temperature.

**Reflected Ripple Current:**
The RMS or peak-to-peak AC current present at the input of the power supply which is a result of the switching frequency of the converter.

**Regulation:**
The ability of a power supply to maintain an output voltage within a specified tolerance as referenced to changing conditions of input voltage and/or load.

**Regulation Band:**
The total error band allowable for an output voltage. This includes the effects of all of the types of regulation: line, load, and cross.
**Remote Inhibit:**
A power supply interface signal, usually TTL compatible, which commands the power supply to shut down one or all outputs.

**Remote Sense:**
Wires connected in parallel with power supply output cables such that the power supply can sense the actual voltage at the load to compensate for voltage drops in the output cables and/or isolation devices.

**Return:**
The designation of the common terminal for the power supply outputs. It carries the return current for the outputs.

**Reverse Voltage Protection:**
A protection circuit that prevents the power supply from being damaged in the event that a reverse voltage is applied at the input or output terminals.

**RFI:**
An abbreviation for Radio Frequency Interference, which is undesirable noise produced by a power supply or other electrical or electronic device during its operation. In power supply technology, RFI is usually taken to mean the same thing as EMI.

**Ripple And Noise:**
The amplitude of the AC component on the DC output of a power supply usually expressed in milli-volts peak-to-peak or RMS.

**Safety Ground:**
A conductive path to earth that is designed to protect persons from electrical shock by shunting away any dangerous currents that might occur due to malfunction or accident.

**Secondary:**
The output section of an isolated power supply which is isolated from the AC mains and specially designed for safety of personnel who might be working with power on the system.

**SELV:**
An abbreviation for Safety Extra Low Voltage, a term generally defined by the regulatory agencies as the highest voltage that can be contacted by a person and not cause injury. It is often specifically defined as 30 VAC or 42.4 VDC.

**Soft Start:**
A technique for gradually activating a power supply circuit when the power supply is first turned on. This technique is generally used to provide a gradual rise in output voltages and inrush current limiting.
Appendix A. Explanation Of Electrical Glossaries

Split Bobbin Winding:
A transformer winding technique where the primary and secondary are wound side-by-side on a bobbin with an insulation barrier between them.

Standby Current:
The input current drawn by a power supply when shut down by a control input (remote inhibit) or under no load.

Switching Frequency:
The rate at which the DC voltage is switched on and off during the pulse width modulation process in a switching power supply.

Temperature Coefficient:
The average output voltage change expressed as a percent per degree centigrade of ambient temperature change. This is usually specified for a predetermined temperature range.

Temperature Derating:
Reducing the output power of a power supply with increasing temperature to maintain reliable operation.

Thermal Protection:
A power supply protection circuit which shuts the power supply down in the event of unacceptably high internal temperatures.

Topology:
The design type of a converter, indicative of the configuration of switching transistors, utilization of the transformer, and type of filtering. Examples of topologies are the Flyback, Forward, Half-Bridge, Full Bridge, and Resonant.

Tracking:
A characteristic in a multiple output power supply where any changes in the output voltage of one output caused by line, load, and/or temperature are proportional to similar changes in accompanying outputs.

Transient Recovery Time:
The time required for an output voltage to be within specified accuracy limits after a step change in line or load conditions.

True Power:
In an AC circuit, true power is the actual power consumed. It is distinguished from apparent power by eliminating the reactive power component that may be present.

Undershoot:
A transient output voltage change which does not meet the low limit of the voltage accuracy specification and is caused by turning the power supply on or off, or abruptly changing line or load conditions.
UPS (Uninterruptible Power Supply):
A power supply which continues to supply power during a loss of input power. Two types are the stand-alone UPS, which is located external to the equipment being powered, and the battery back-up power supply, which is embedded in the equipment being powered.

Voltage Balance:
The difference in magnitudes, in percent, of two output voltages that have equal nominal voltage magnitudes but opposite polarities.

Voltage Mode:
A method of closed loop control of a switching converter where the pulse width is varied in response to changes in the output voltage to regulate the output.

Warm-Up Drift:
The initial change in the output voltage of a power supply in the time period between turn-on and when the power supply reaches thermal equilibrium at 25 degrees Centigrade, full load and nominal line.

Warm-Up Time:
The time required after initial turn on for a power supply to achieve compliance to its performance specifications.

### Note:

1. These plugs can’t transform the voltage level.
2. Although this table classifies the plugs and voltage levels for different countries, please still confirm it before using.

### Plug Styles:

- **A. Flat Shape Plug**
  - Flat Shape Plug-Φ  Flat Plug-Φ  Flat Shape Outlet 6A

- **B. Circle Shape Plug**
  - Circle Shape Plug - Flat Shape Outlet 6A

- **C. Oblique-Flat Plug**
  - Oblique-Flat Plug- Flat Plug-Φ  Flat Shape Outlet

- **D. Three-Leg Plug**
  - Three Leg Plug Flat Shape-Φ  Flat Shape Outlet 13A

- **E. Three-Leg Plug (North America)**
  - Three Leg Plug Flat Shape 4Φ  Flat Shape Outlet 13A

Total maximum output power: __________ Watt.

Note: 1. Output (V): Refer to a nominal DC voltage which appears between output terminals.
2. Rated (A): Refer to the rated current from power supply to load.
3. Min.(A)~Max.(A): The minimum and maximum current from power supply to load.
4. Peak(A): The applicable short period for _________ms current from power about supply to load.
5. Output Power(W): Refer to output (V) × Rated (A).

2.2 Regulation, Accuracy and Ripple/noise

</tbody>
</table>

Note: Please fill in the appropriate values for each parameter.
Note: 1: Line Regulation: The maximum fluctuation of output voltage for input voltage range changed from low line to high line.

2: Load Regulation: The maximum fluctuation of output voltage for loading current changed from minimum load to rated load.
and keep other load at 60% of rated load.

3: Accuracy Range: The output voltage is refer to tolerance that including initial set up tolerance, line regulation and load regulation.

4: Ripple/Noise: The ripple and noise is tested by 20MHz band width limited oscilloscope and terminated each output with a 0.1uF & 47uF capacitor.

3.0 INPUT SPECIFICATIONS

3.1 Input Voltage Range
☐ 88 Vac to 264 Vac. (Universal /Full Range)

☐ 88 ~ 132 Vac and 176 ~ 264 Vac. (Auto Ranging)

☐ 88 ~ 132 Vac and 176 ~ 264 Vac. (Selectable by □) switch or □ Jumper)

3.2 Input Frequency Range
47 Hz to 63 Hz.

3.3 Power Factor Correction
☐ The P.F.C. require________at 115Vac; _______at 230Vac

☐ Non P.F.C. requirement.

3.4 Input Leakage Current
Input leakage current is maximum ______ MA at 115 Vac input or ______ mA at 230 Vac input.

3.5 Inrush Current
The inrush current does not exceed ______ A at 115 Vac input or ______ A at 230 Vac input, at cold start and 25 degree C ambient.
4.0 GENERAL FEATURES

4.1 Efficiency: ________ %.
This is the ratio of output power to input dissipation power. When tested at nominal input and rated load, at 25 degree C ambient.

4.2 Hold up time:
The output will remain within regulation limit for ________ ms, after loss of AC power when operating at ________ Vac input and rated load.

4.3 Protection

4.3.1 Over voltage protection
To prevent output voltage exceeding a fixed value and damaged to external load. The protection circuit will automatically shut down the output.
The trip point of O.V.P. circuit is from _____ V to _____ V (for main output).

4.3.2 Short circuit or over load protection
The power supply will be protected against short circuit or over load Condition. When cause of activation of short circuit or over load is removed, the power supply will be automatically recovered.

4.4 Power good / fail signal

[ ] Power good signal is a TTL compatible signal, which will go high with a delay of Between ___100__ ms to ___500__ ms after main output has reached 90% of it's nominal output value.

[ ] Power fail signal is a TTL compatible signal, which will go low at least ___1___ms before output voltage fall below 90% of it's nominal value.

[ ] Non Requirement.

4.5 Other Feature

[ ] Remote On/Off: The power supply output is controlled by TTL signal comes from system. High is off state, Low is on state.

[ ] Thermal Protection: The power supply output will be shut down when inside of working temperature reached higher than _____ degree C.
5.0 ENVIRONMENT SPECIFICATIONS

5.1 Operating temperature range

__________ Degree C to __________ Degree C

5.2 Storage temperature range

__________ Degree C to __________ Degree C

5.3 Humidity

__________ % to __________ % non condensing.

6.0 INTERNATIONAL STANDARDS

6.1 Safety agency approval

Designed to meet the following standards:

☐ UL60950 (Safety for Information Technology Equipment)

☐ EN60950 (Safety for Information Technology Equipment)

☐ IEC-60601 (Safety for Medical Equipment)

☐ Safety requirement unnecessary

☐ Others requirements ________________________________

6.2 EMC Requirement

☐ FCC Part 15, Subpart J, Class [ ] A [ ] B

☐ EN 55022 Class [ ] A [ ] B (Equal CISPR 22)

☐ EN 61000-3-2 (Harmonic Current Emission)

☐ EN 61000-3-3 (Voltage Fluctuations and Flicker)

☐ EN61000-4-2 (ESD Immunity)

☐ EN61000-4-3 (RF Radiated Fields Immunity)

☐ EN61000-4-4 (EFT/Burst Immunity)

☐ EN61000-4-5 (Surge Immunity)

☐ EN61000-4-6 (RF Common Mode Immunity)

☐ EN61000-4-8 (Power Frequency Magnetic Field Immunity)

☐ EN61000-4-11 (Voltage Interruptions and Voltage Dips Immunity)

☐ Others requirements ________________________________
7.0 MECHANICAL SPECIFICATIONS

7.1 Type:
- [ ] P.C.B Board
- [ ] Enclosed case
- [ ] U-Bracket
- [ ] L-Bracket

7.2 Dimensions shown in mm by L*W*H. (Fix hole of diameter and Mechanical drawing attached is required).

7.3 Connector Type
- Input: Type: ________ Pitch: ________
- Output: Type: ________ Pitch: ________

7.4 Cooling
- [ ] Cooling Fan is mounted on system case, ______ CFM.
- [ ] Cooling Fan is required on Power Supply.
- [ ] Natural Convection.
  Note: Cooling fan is installed in enclosure of power supply and mechanical drawing attached is required.

7.5 Input / output pin assignment and wiring specification:
